Clinical Evidence The typical course of HBO_2T consists of 30 once-daily compressions to 202.6–243.1 kPa (2–2.4 ATA) for 1.5–2 h each session, often bracketed around surgical intervention if required. Although HBO_2T has been used for LRTI since at least 1975, most clinical studies have been limited to small case series or individual case reports. In a review, Feldmeier and Hampson located 71 such reports involving a total of 1193 patients across eight different tissues. There were clinically significant improvements in the majority of patients, and only 7 of 71 reports indicated a generally poor response to HBO_2T. A Cochrane systematic review with meta-analysis included six randomized trials published since 1985 and drew the following conclusions (see Table 477e-2 for numbers needed to treat): HBO_2T improves healing in radiation proctitis (relative risk [RR] of healing with HBO_2T 2.7; 95% confidence interval [CI] 1.2–6) and after hemimandibulectomy and reconstruction of the mandible (RR 1.4; 95% CI 1.1–1.8); HBO_2T improves the probability of achieving mucosal coverage (RR 1.4; 95% CI 1.2–1.6) and the restoration of bony continuity with osteoradionecrosis (ORN) (RR 1.4; 95% CI 1.1–1.8); HBO_2T prevents the development of ORN following tooth extraction from a radiation field (RR 1.4; 95% CI 1.08–1.7) and reduces the risk of wound dehiscence following grafts and flaps in the head and neck (RR 4.2; 95% CI 1.1–16.8). Conversely, there was no evidence of benefit in established radiation brachial plexus lesions or brain injury.

SELECTED PROBLEM WOUNDS

A problem wound is any cutaneous ulceration that requires a prolonged time to heal, does not heal, or recurs. In general, wounds referred to hyperbaric facilities are those where sustained attempts to heal by other means have failed. Problem wounds are common and constitute a significant health problem. It has been estimated that 1% of the population of industrialized countries will experience a leg ulcer at some time. The global cost of chronic wound care may be as high as U.S. $25 billion per year.

Pathology and Clinical Course By definition, chronic wounds are indolent or progressive and resistant to the wide array of treatments applied. Although there are many contributing factors, most commonly these wounds arise in association with one or more comorbidities such as diabetes, peripheral venous or arterial disease, or prolonged pressure (decubitus ulcers). First-line treatments are aimed at correction of the underlying pathology (e.g., vascular reconstruction, compression bandaging, or normalization of blood glucose level), and HBO_2T is an adjunctive therapy to good general wound care practice to maximize the chance of healing.

TABLE 477e-2 SELECTED INDICATIONS FOR WHICH THERE IS PROMISING EFFICACY FOR THE APPLICATION OF HYPERBARIC OXYGEN THERAPY

Diagnosis	Outcome (number of sessions)	NNT 95% CI	Estimated Cost to Produce One Extra Favorable Outcome 95% CI (USD)	Comments and Recommendations
Radiation tissue injury	**More information is required on the subset of disease severity, the affected tissue type that is most likely to benefit, and the time over which benefit may persist.**			
	Resolved proctitis (30)	3	22,392	Large ongoing multicenter trial
		2–11	14,928–82,104	
	Healed mandible (30)	4	29,184	Based on one poorly reported study
		2–8	14,592–58,368	
	Mucosal cover in ORN (30)	3	29,888	Based on one poorly reported study
		2–4	14,592–29,184	
	Bony continuity in ORN (30)	4	29,184	Based on one poorly reported study
		2–8	14,592–58,368	
	Prevention of ORN after dental extraction (30)	4	29,184	Based on a single study
		2–13	14,592–94,848	
	Prevention of dehiscence (30)	5	36,480	Based on one poorly reported study
		3–8	21,888–58,368	
Chronic wounds	**More information is required on the subset of disease severity or classification most likely to benefit, the time over which benefit may persist, and the most appropriate oxygen dose. Economic analysis is required.**			
	Diabetic ulcer healed at 1 year (30)	2	14,928	Based on one small study, more research required
		1–5	7464–37,320	
	Diabetic ulcer, major amputation avoided (30)	4	29,856	Three small studies; outcome over a longer time period required
		3–11	22,392–82,104	
ISSNHL	**No evidence of benefit more than 2 weeks after onset. More research is required to define the role (if any) of HBO_2T in routine therapy.**			
	Improvement of 25% in hearing loss within 2 weeks of onset (15)	5	18,240	Some improvement in hearing, but functional significance unknown
		3–20	10,944–72,960	
Acute coronary syndrome	**More information is required on the subset of disease severity and timing of therapy most likely to result in benefit. Given the potential of HBO_2T in modifying ischemia-reperfusion injury, attention should be given to the combination of HBO_2T and thrombolysis in early management and in the prevention of restenosis after stent placement.**			
	Episode of MACE (5)	4	4864	Based on a single small study; more research required
		3–10	3648–12,160	
		6	7296	
	Incidence of significant dysrhythmia (5)	3–24	3648–29,184	Based on a single moderately powered study in the 1970s
Traumatic brain injury	**Limited evidence that for acute injury HBO_2T reduces mortality but not functional morbidity. Routine use not yet justified.**			
	Mortality (15)	7	34,104	Based on four heterogeneous studies
		4–22	19,488–58,464	
Enhancement of radiotherapy	**There is some evidence that HBO_2T improves local tumor control, reduces mortality for cancers of the head and neck, and reduces the chance of local tumor recurrence in cancers of the head, neck, and uterine cervix.**			
	Head and neck cancer:	5	14,592	Based on trials performed in the 1970s and 1980s. There may be some confounding by radiation fractionation schedule
	5-year mortality (12)	3–14	8755–40,858	
	Local recurrence 1 year (12)	5	14,592	May no longer be relevant to therapy
		4–8	11,674–23,347	
	Cancer of uterine cervix:	5	24,320	As above
	Local recurrence at 2 years (20)	4–8	19,456–38,912	
Decompression illness[a]	**Reasonable evidence for reduced number of HBO_2T sessions but similar outcomes when NSAID added.**			
	Reduction of HBO_2T treatment requirement by 1	5	N/R	Single appropriately powered randomized trial
		3–18		

[a]Tenoxicam used as an adjunct to recompression on oxygen.

Abbreviations: CI, confidence interval; HBO_2T, hyperbaric oxygen therapy; ISSNHL, idiopathic sudden sensorineural hearing loss; MACE, major adverse cardiac events; N/R, not remarkable; NNT, number needed to treat; NSAID, nonsteroidal anti-inflammatory drug; ORN, osteoradionecrosis; USD, U.S. dollars.

For most indolent wounds, hypoxia is a major contributor to failure to heal. Many guidelines to patient selection for HBO_2T include the interpretation of transcutaneous oxygen tensions around the wound while breathing air and oxygen at pressure (Fig. 477e-4). Wound healing is a complex and incompletely understood process. While it appears that in acute wounds healing is stimulated by the initial hypoxia, low pH, and high lactate concentrations found in freshly injured tissue, some elements of tissue repair are extremely oxygen dependent, for example, collagen elaboration and deposition by fibroblasts, and bacterial killing by macrophages. In this complicated interaction between wound hypoxia and peri-wound oxygenation, successful healing relies on adequate tissue oxygenation in the area surrounding the fresh wound. Certainly, wounds that lie in hypoxic tissue beds are those that most often display poor or absent healing. Some causes of tissue hypoxia will be reversible with HBO_2T, whereas some will not (e.g., in the presence of severe large vessel disease). When tissue hypoxia can be overcome by a high driving pressure of oxygen in the arterial blood, this can be demonstrated by measuring the tissue partial pressure of oxygen using an implantable oxygen electrode or, more commonly, a modified transcutaneous Clarke electrode.

The intermittent presentation of oxygen to those hypoxic tissues facilitates a resumption of healing. These short exposures to high oxygen tensions have long-lasting effects (at least 24 h) on a wide range of healing processes (Fig. 477e-3). The result is a gradual improvement in oxygen tension around the wound that reaches a plateau in experimental studies at about 20 treatments over 4 weeks. Improvements in oxygenation are associated with an eight- to ninefold increase in vascular density over both normobaric oxygen and air-breathing controls.

Clinical Evidence The typical course of HBO_2T consists of 20–30 once-daily compressions to 2–2.4 ATA for 1.5–2 h each session, but is highly dependent on the clinical response. There are many case series in the literature supporting the use of HBO_2T for a wide range of problem wounds. Both retrospective and prospective cohort studies suggest that 6 months after a course of therapy, about 70% of indolent ulcers will be substantially improved or healed. Often these ulcers have been present for many months or years, suggesting that the application of HBO_2T has a profound effect, either primarily or as a facilitator of other strategies. A recent Cochrane review included nine randomized controlled trials (RCTs) and concluded that the chance of ulcer healing improved about fivefold with HBO_2T (RR 5.20; 95% CI 1.25–21.66; $p = .02$). Although there was a trend to benefit with HBO_2T, there was no statistically significant difference in the rate of major amputations (RR 0.36; 95% CI 0.11–1.18).

CARBON MONOXIDE POISONING

Carbon monoxide (CO) is a colorless, odorless gas formed during incomplete hydrocarbon combustion. Although CO is an essential endogenous neurotransmitter linked to NO metabolism and activity, it is also a leading cause of poisoning death, and in the United States alone results in more than 50,000 emergency department visits per year and about 2000 deaths. Although there are large variations from country to country, about half of nonlethal exposures are due to self-harm. Accidental poisoning is commonly associated with defective or improperly installed heaters, house fires, and industrial exposures. The motor vehicle is by far the most common source of intentional poisoning.

Pathology and Clinical Course The pathophysiology of carbon monoxide exposure is incompletely understood. CO binds to hemoglobin with an affinity more than 200 times that of oxygen, directly reducing the oxygen-carrying capacity of blood, and further promoting tissue hypoxia by shifting the oxyhemoglobin dissociation curve to the left. CO is also an anesthetic agent that inhibits evoked responses and narcotizes experimental animals in a dose-dependent manner. The associated loss of airway patency together with reduced oxygen carriage in blood may cause death from acute arterial hypoxia in severe poisoning. CO may also cause harm by other mechanisms including direct disruption of cellular oxidative processes, binding to myoglobin and hepatic cytochromes, and peroxidation of brain lipids.

The brain and heart are the most sensitive target organs due to their high blood flow, poor tolerance of hypoxia, and high oxygen requirements. Minor exposure may be asymptomatic or present with vague constitutional symptoms such as headache, lethargy, and nausea, whereas higher doses may present with poor concentration and cognition, short-term memory loss, confusion, seizures, and loss of consciousness. While carboxyhemoglobin (COHb) levels on admission do not necessarily reflect the severity or the prognosis of CO poisoning, cardiorespiratory arrest carries a very poor prognosis. Over the longer term, surviving patients commonly have neuropsychological sequelae. Motor disturbances, peripheral neuropathy, hearing loss, vestibular abnormalities, dementia, and psychosis have all been reported. Risk

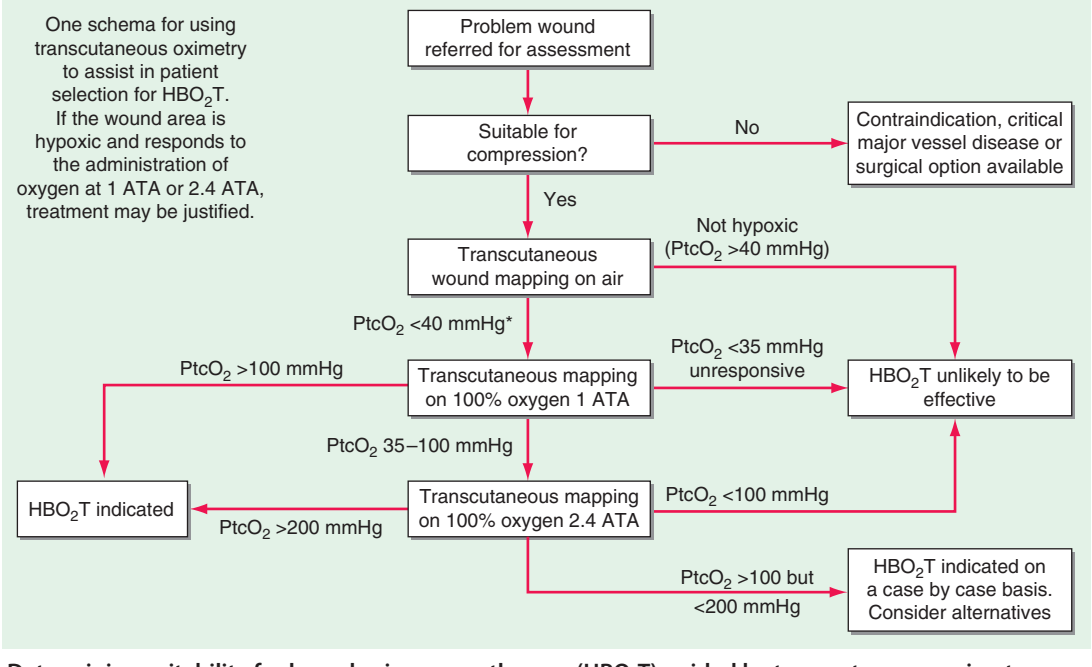

FIGURE 477e-4 Determining suitability for hyperbaric oxygen therapy (HBO_2T) guided by transcutaneous oximetry around the wound bed. *In diabetic patients, <50 mmHg may be more appropriate. $PtcO_2$, transcutaneous oxygen pressure.

factors for poor outcome are age >35 years, exposure for >24 h, acidosis, and loss of consciousness.

Clinical Evidence The typical course of HBO_2T consists of two to three compressions to 2–2.8 ATA for 1.5–2 h each session. It is common for the first two compressions to be delivered within 24 h of the exposure. CO poisoning is one of the longest-standing indications for HBO_2T—based largely on the obvious connection between exposure, tissue hypoxia, and the ability of HBO_2T rapidly to overcome this hypoxia. CO is eliminated rapidly via the lungs on application of HBO_2T, with a half-life of about 21 min at 2.0 ATA versus 5.5 h breathing air and 71 min breathing oxygen at sea level. In practice, however, it seems unlikely that HBO_2T can be delivered in time to prevent either acute hypoxic death or irreversible global cerebral hypoxic injury. If HBO_2T is beneficial in CO poisoning, it must reduce the likelihood of persisting and/or delayed neurocognitive deficit through a mechanism other than the simple reversal of arterial hypoxia due to high levels of COHb. The difficulty in accurately assessing neurocognitive deficit has been one of the primary sources of controversy surrounding the clinical evidence in this area. To date there have been six randomized controlled trials of HBO_2T for CO poisoning, although only four have been reported in full. While a Cochrane review suggested that overall there is insufficient evidence to confirm a beneficial effect of HBO_2T on the chance of persisting neurocognitive deficit following poisoning (34% of patients treated with oxygen at 1 atmosphere vs 29%, of those treated with HBO_2T; odds ratio [OR] 0.78; 95% CI 0.54–1.1), this may have more to do with poor reporting and inadequate follow-up than with evidence that HBO_2T is not effective. The interpretation of the literature has much to do with how one defines neurocognitive deficit. In the most methodologically rigorous of these studies (Weaver et al.), a professionally administered battery of validated neuropsychological tests and a definition based on the deviation of individual subtest scores from the age-adjusted normal values was used; if the patient complained of memory, attention, or concentration difficulties, the required decrement was decreased. Using this approach, 6 weeks after poisoning, 46% of patients treated with normobaric oxygen alone had cognitive sequelae compared to 25% of those who received HBO_2T (p = .007; number needed to treat [NNT] = 5; 95% CI 3–16). At 12 months, the difference remained significant (32% vs 18%; p = .04; NNT = 7; 95% CI 4–124) despite considerable loss to follow-up.

On this basis, HBO_2T remains widely advocated for the routine treatment of patients with moderate to severe poisoning—in particular in those older than 35 years, presenting with a metabolic acidosis on arterial blood-gas analysis, exposed for lengthy periods, or with a history of unconsciousness. Conversely, many toxicologists remain unconvinced about the place of HBO_2T in this situation and call for further well-designed studies.

DIVING MEDICINE

INTRODUCTION

Underwater diving is both a popular recreational activity and a means of employment in a range of tasks from underwater construction to military operations. It is a complex activity with unique hazards and medical complications arising mainly as a consequence of the dramatic changes in pressure associated with both descent and ascent through the water column. For every 10.13 m increase in depth of seawater, the ambient pressure (P_{amb}) increases by 101.3 kPa (1 atmosphere) so that a diver at 20 m depth is exposed to a P_{amb} of approximately 303.9 kPa (3 ATA), made up of 1 ATA due to atmospheric pressure and 2 ATA generated by the water column.

BREATHING EQUIPMENT

Most diving is undertaken using a self-contained underwater breathing apparatus (scuba) consisting of one or more cylinders of compressed gas connected to a pressure-reducing regulator and a demand valve activated by inspiratory effort. Some divers use "rebreathers," which are scuba devices that are closed or semiclosed circle systems with a carbon dioxide scrubber and a system designed to maintain a safe inspired PO_2. Exhaled gas is recycled, and gas consumption is limited to little more than the oxygen metabolized by the diver. Rebreathers are therefore popular for deep dives where expensive helium is included in the respired mix (see below). Occupational divers frequently use "surface supply" equipment where gas, along with other utilities such as communications and power, is supplied via an umbilical from the surface.

All these systems must supply gas to the diver at the P_{amb} of the surrounding water or inspiration would be impossible against the surrounding water pressure. For most recreational diving, the respired gas is air. Pure oxygen is rarely used because oxygen may provoke seizures above an inspired PO_2 of 162 kPa (1.6 ATA) in aquatic environments, limiting the practical safe depth to 6 m. This is a conspicuously lower PO_2 than routinely used for hyperbaric therapy, reflecting a higher risk of both seizures and pulmonary toxicity during immersion. For the same reason, very deep diving requires the use of oxygen fractions lower than in air (FO_2 0.21). This is because breathing air at 66 m means inspiring 1.6 ATA of oxygen, the maximum allowable pressure. To dive any deeper, breathing gases must contain less oxygen than air. Deep-diving gases often include helium instead of nitrogen to reduce both the narcotic effect and high gas density that result from breathing nitrogen at high pressures.

SUITABILITY FOR DIVING

The most common reason for physician consultation in relation to diving is for the evaluation of suitability for diver training or after a health event. Occupational diver candidates are usually compelled to see doctors with specialist training in the field, both at entry to the industry and periodically thereafter, and their medical evaluations are usually conducted according to legally mandated standards. In contrast, in most jurisdictions prospective recreational diver candidates simply complete a self-assessment medical questionnaire prior to diver training. If there are no positive responses, the candidate proceeds directly to training, but positive responses mandate the candidate see a doctor for evaluation of the identified medical issue. Prospective divers will often present to their family medicine practitioner for this purpose. In the modern era, such consultations have evolved from a simple proscriptive exercise of excluding those with potential contraindications to a more "risk analysis" approach in which each case is evaluated on its own merits. Such analyses require integration of diving physiology, the impact of associated medical problems, and a detailed knowledge of the specific medical condition of the candidate. A detailed discussion of the subject is beyond the scope of this chapter, but a few important principles are outlined below.

There are three primary questions that should be answered: (1) Could the underlying condition be exacerbated by diving? (2) Could the condition make a diving medical problem more likely? (3) Could the condition prevent the diver from meeting the functional requirements of diving? As examples, epilepsy is usually considered a contraindication because there are epileptogenic stimuli encountered in diving that could make a seizure more likely (such as thermal stress and exercise). Active asthma is a relative contraindication because it could predispose to pulmonary barotrauma (see below), and untreated ischemic heart disease is a contraindication because it could prevent a diver from exercising sufficiently to get out of a difficult situation such as being caught in a current. It can be a complex matter to recognize the relevant interactions between diving and medical conditions and to determine the impact on suitability for diving. Physicians interested in regularly conducting such evaluations should obtain relevant training. Short courses providing relevant training are offered by specialist groups in most countries.

BAROTRAUMA

The problem of middle-ear barotrauma (MEBT) with diving is similar to the problem that may occur during descent from altitude in an airplane, but difficulties with equalizing pressure in the middle ear are exaggerated underwater by both the rapidity and magnitude of pressure change as a diver descends or ascends. Failure to periodically insufflate the middle-ear spaces via the eustachian tubes during descent results in increasing pain. As the P_{amb} increases, the tympanic membrane (TM)

may be bruised or even ruptured as it is pushed inward. Negative pressure in the middle ear results in engorgement of blood vessels in the mucous membranes and leads to effusion or bleeding, which can be associated with a *conductive* hearing loss. MEBT is much less common during ascent because expanding gas in the middle-ear space tends to open the eustachian tube easily and "automatically." Barotrauma may also affect the respiratory sinuses, although the sinus ostia are usually widely patent and allow automatic pressure equalization without the need for specific maneuvers. If equalization fails, pain usually results in termination of the dive. Difficulty with equalizing ears or sinuses may respond to oral or nasal decongestants.

Much less commonly the inner ear may suffer barotrauma (IEBT). Several explanations have been proposed, of which the most favored holds that forceful attempts to insufflate the middle-ear space by Valsalva maneuvers during descent cause sudden transmission of pressure to the perilymph via the cochlear aqueduct and outward rupture of the round window already under tension because of negative middle ear pressure. The clinician should be alerted to possible IEBT after diving by a *sensorineural* hearing loss or true vertigo (which is often accompanied by nausea, vomiting, nystagmus, and ataxia). These manifestations can also occur in vestibulocochlear DCS (see below) but should never be attributed to MEBT. Immediate review by an expert diving physician is recommended, and urgent referral to an otologist will often follow.

The lungs are also vulnerable to barotrauma but are at most risk during ascent. If expanding gas becomes trapped in the lungs as P_{amb} falls, this may rupture alveoli and associated vascular tissue. Gas trapping may occur if divers intentionally or involuntarily hold their breath during ascent or if there are bullae. The extent to which asthma predisposes to pulmonary barotrauma is debated, but the presence of active bronchoconstriction must increase risk. For this reason, asthmatics who regularly require bronchodilator medications or whose airways are sensitive to exercise or cold air are usually discouraged from diving. While possible consequences of pulmonary barotrauma include pneumothorax and mediastinal emphysema, the most feared is the introduction of gas into the pulmonary veins leading to cerebral arterial gas embolism (CAGE). Manifestations of CAGE include loss of consciousness, confusion, hemiplegia, visual disturbances, and speech difficulties, appearing immediately or within minutes after surfacing. The management is the same as for DCS described below. It is notable that the natural history of CAGE often includes substantial or complete resolution of symptoms early after the event. This is probably the clinical correlate of bubble involution and redistribution with consequent restoration of flow. Patients exhibiting such remissions should still be reviewed at specialist diving medical centers because secondary deterioration or reembolization can occur. Unsurprisingly, these events can be misdiagnosed as typical strokes or transient ischemic attacks (TIAs) (Chap. 455) when patients are seen by those unfamiliar with diving medicine. *All patients presenting with neurologic symptoms after diving should have their symptoms discussed with a specialist in diving medicine and be considered for recompression therapy.*

DECOMPRESSION SICKNESS

DCS is caused by the formation of bubbles from dissolved inert gas (usually nitrogen) during or after ascent (decompression) from a compressed gas dive. Bubble formation is also possible following decompression for extravehicular activity during space flight and with ascent to altitude in unpressurized aircraft. DCS in the latter scenarios is probably rare in comparison with diving, where the incidence is approximately 1:10,000 recreational dives.

Breathing at elevated P_{amb} results in increased uptake of inert gas into blood and then into tissues. The rate at which tissue inert gas equilibrates with the inspired inert gas pressure is proportional to tissue blood flow and the blood-tissue partition coefficient for the gas. Similar factors dictate the kinetics of inert gas washout during ascent. If the rate of gas washout from tissues does not match the rate of decline in P_{amb}, then the sum of dissolved gas pressures in the tissue will exceed P_{amb}, a condition referred to as "supersaturation." This is the prerequisite for bubbles to form during decompression, although other less well-understood factors are also involved. Deeper and longer dives result in greater inert gas absorption and greater likelihood of tissue supersaturation during ascent. Divers control their ascent for a given depth and time exposure using algorithms that often include periods where ascent is halted for a prescribed period at different depths to allow time for gas washout ("decompression stops"). Although a breach of these protocols increases the risk of DCS, adherence does not guarantee against it. DCS should be considered in any diver manifesting symptoms not readily explained by an alternative mechanism.

Bubbles may form within tissues themselves, where they cause symptoms by mechanical distraction of pain-sensitive or functionally important structures. They also appear in the venous circulation as blood passes through supersaturated tissues. Some venous bubbles are tolerated without symptoms and are filtered from the circulation in the pulmonary capillaries. However, in sufficiently large numbers, these bubbles are capable of inciting inflammatory and coagulation cascades, damaging endothelium, activating formed elements of blood such as platelets, and causing symptomatic pulmonary vascular obstruction. Moreover, if there is a right-to-left shunt such as through a patent foramen ovale (PFO) or an intrapulmonary shunt, then venous bubbles may enter the arterial circulation (25% of adults have a probe-patent PFO). The risk of cerebral, spinal cord, inner ear, and skin manifestations appears higher in the presence of significant shunts, suggesting that these "arterialized" venous bubbles can cause harm, perhaps by disrupting flow in the microcirculation of target organs. Circulating endothelial microparticles, which are elevated in number and size after diving, are currently under investigation as indicators of decompression stress or possibly as injurious agents in their own right. How they arise, and their role in DCS, remain unclear.

Table 477e-3 lists manifestations of DCS grouped according to organ system. The majority of cases present with mild symptoms, including musculoskeletal pain, fatigue, and minor neurologic manifestations such as patchy paresthesias. Serious presentations are much less common. Pulmonary and cardiovascular manifestations can be

TABLE 477e-3 MANIFESTATIONS OF DECOMPRESSION SICKNESS

Organ System	Manifestations
Musculoskeletal	Limb pain
Neurologic	
Cerebral	Confusion
	Visual disturbances
	Speech disturbances
Spinal	Muscular weakness
	Paralysis
	Upper motor neuron signs
	Bladder and sphincter dysfunction
	Dermatomal sensory disturbances
	Abdominal pain
	Girdle pain
Vestibulocochlear	Hearing loss
	Vertigo and ataxia
	Nausea and vomiting
Peripheral	Patchy nondermatomal sensory disturbance
Pulmonary	Cough
	Dyspnea
	Pulmonary edema (rare)
Cardiovascular	Chest pain
	Arrhythmia
	Hemoconcentration
	Coagulopathy
	Hypotension
Cutaneous	Rash, itch
Lymphatic	Soft tissue edema, often relatively localized
Constitutional	Fatigue and malaise

life-threatening, and spinal cord involvement frequently results in permanent disability. Latency is variable. Serious DCS usually manifests within minutes of surfacing, but mild symptoms may not appear for several hours. Symptoms arising more than 24 h after diving are very unlikely to be DCS. The presentation may be confusing and nonspecific, and there are as yet no useful diagnostic investigations. Diagnosis is based on integration of findings from examination of the dive profile, the nature and temporal relationship of symptoms, and the clinical examination. Some DCS presentations may be difficult to separate from CAGE following pulmonary barotrauma, but from a clinical perspective the distinction is unimportant because the first aid and definitive management of both conditions are the same.

TREATMENT DIVING MEDICINE

First aid includes horizontal positioning (especially if there are cerebral manifestations), intravenous fluids if available, and sustained 100% oxygen administration. The latter accelerates inert gas washout from tissues and promotes resolution of bubbles. Definitive treatment of DCS or CAGE with recompression and hyperbaric oxygen is justified in most instances, although some mild or marginal DCS cases may be managed with first aid measures, an option that may be invoked under various circumstances, but especially if evacuation for recompression is hazardous or extremely difficult. Long-distance evacuations are usually undertaken using a helicopter flying at low altitude or a fixed wing air ambulance pressurized to 1 atmosphere pressure.

Recompression reduces bubble volume in accordance with Boyle's law and increases the inert gas partial pressure difference between a bubble and surrounding tissue. At the same time, oxygen administration markedly increases the inert gas partial pressure difference between alveoli and tissue. The net effect is to significantly increase the rate of inert gas diffusion from bubble to tissue and tissue to blood, thus accelerating bubble resolution. Hyperbaric oxygen also helps oxygenate compromised tissues and appears to ameliorate some of the proinflammatory effects of bubbles. Various recompression protocols have been advocated, but there are no data that define the optimum approach. It typically begins with oxygen administered at 2.8 atmospheres absolute, the maximum pressure at which the risk of oxygen toxicity remains acceptable in a hyperbaric chamber. There follows a stepwise decompression over variable periods adjusted to symptom response. The most widely used algorithm is the U.S. Navy Table 6, whose shortest format lasts 4 h and 45 min. Typically, shorter "follow-up" recompressions are repeated daily while symptoms persist and appear responsive to treatment. Adjuncts to recompression include intravenous fluids and other supportive care as necessary. Occasionally, very sick divers require high-level intensive care.

478e Hypothermia and Frostbite

Daniel F. Danzl

HYPOTHERMIA

Accidental hypothermia occurs when there is an unintentional drop in the body's core temperature below 35°C (95°F). At this temperature, many of the compensatory physiologic mechanisms that conserve heat begin to fail. *Primary accidental hypothermia* is a result of the direct exposure of a previously healthy individual to the cold. The mortality rate is much higher for patients who develop *secondary hypothermia* as a complication of a serious systemic disorder.

CAUSES

Primary accidental hypothermia is geographically and seasonally pervasive. Although most cases occur in the winter months and in colder climates, this condition is surprisingly common in warmer regions as well. Multiple variables render individuals at the extremes of age—both the elderly and neonates—particularly vulnerable to hypothermia (Table 478e-1). The elderly have diminished thermal perception and are more susceptible to immobility, malnutrition, and systemic illnesses that interfere with heat generation or conservation. Dementia, psychiatric illness, and socioeconomic factors often compound these problems by impeding adequate measures to prevent hypothermia. Neonates have high rates of heat loss because of their increased surface-to-mass ratio and their lack of effective shivering and adaptive behavioral responses. At all ages, malnutrition can contribute to heat loss because of diminished subcutaneous fat and as a result of depleted energy stores used for thermogenesis.

Individuals whose occupations or hobbies entail extensive exposure to cold weather are at increased risk for hypothermia. Military history is replete with hypothermic tragedies. Hunters, sailors, skiers, and climbers also are at great risk of exposure, whether it involves injury, changes in weather, or lack of preparedness.

Ethanol causes vasodilation (which increases heat loss), reduces thermogenesis and gluconeogenesis, and may impair judgment or lead to obtundation. Phenothiazines, barbiturates, benzodiazepines, heterocyclic antidepressants, and many other medications reduce centrally mediated vasoconstriction. Up to 25% of patients admitted to an intensive care unit because of drug overdose are hypothermic. Anesthetics can block shivering responses; their effects are compounded when patients are not insulated adequately in the operating or recovery units.

TABLE 478e-1 RISK FACTORS FOR HYPOTHERMIA

Age extremes	Endocrine-related
Elderly	Diabetes mellitus
Neonates	Hypoglycemia
Environmental exposure	Hypothyroidism
Occupational	Adrenal insufficiency
Sports-related	Hypopituitarism
Inadequate clothing	Neurologic
Immersion	Cerebrovascular accident
Toxicologic and pharmacologic	Hypothalamic disorders
Ethanol	Parkinson's disease
Phenothiazines	Spinal cord injury
Barbiturates	Multisystemic
Anesthetics	Trauma
Neuromuscular blockers	Sepsis
Antidepressants	Shock
Insufficient fuel	Hepatic or renal failure
Malnutrition	Carcinomatosis
Marasmus	Burns and exfoliative dermatologic disorders
Kwashiorkor	Immobility or debilitation

Several types of endocrine dysfunction can lead to hypothermia. Hypothyroidism—particularly when extreme, as in myxedema coma—reduces the metabolic rate and impairs thermogenesis and behavioral responses. Adrenal insufficiency and hypopituitarism also increase susceptibility to hypothermia. Hypoglycemia, most commonly caused by insulin or oral hypoglycemic drugs, is associated with hypothermia, in part because of neuroglycopenic effects on hypothalamic function. Increased osmolality and metabolic derangements associated with uremia, diabetic ketoacidosis, and lactic acidosis can lead to altered hypothalamic thermoregulation.

Neurologic injury from trauma, cerebrovascular accident, subarachnoid hemorrhage, and hypothalamic lesion increases susceptibility to hypothermia. Agenesis of the corpus callosum (*Shapiro syndrome*) is one cause of episodic hypothermia; in this syndrome, profuse perspiration is followed by a rapid fall in temperature. Acute spinal cord injury disrupts the autonomic pathways that lead to shivering and prevents cold-induced reflex vasoconstrictive responses.

Hypothermia associated with sepsis is a poor prognostic sign. Hepatic failure causes decreased glycogen storage and gluconeogenesis as well as a diminished shivering response. In acute myocardial infarction associated with low cardiac output, hypothermia may be reversed after adequate resuscitation. With extensive burns, psoriasis, erythrodermas, and other skin diseases, increased peripheral-blood flow leads to excessive heat loss.

THERMOREGULATION

Heat loss occurs through five mechanisms: radiation (55–65% of heat loss), conduction (10–15% of heat loss, much increased in cold water), convection (increased in the wind), respiration, and evaporation; both of the latter two mechanisms are affected by the ambient temperature and the relative humidity.

The preoptic anterior hypothalamus normally orchestrates thermoregulation (Chap. 23). The immediate defense of thermoneutrality is via the autonomic nervous system, whereas delayed control is mediated by the endocrine system. Autonomic nervous system responses include the release of norepinephrine, increased muscle tone, and shivering, leading to thermogenesis and an increase in the basal metabolic rate. Cutaneous cold thermoreception causes direct reflex vasoconstriction to conserve heat. Prolonged exposure to cold also stimulates the thyroid axis, leading to an increased metabolic rate.

CLINICAL PRESENTATION

In most cases of hypothermia, the history of exposure to environmental factors (e.g., prolonged exposure to the outdoors without adequate clothing) makes the diagnosis straightforward. In urban settings, however, the presentation is often more subtle, and other disease processes, toxin exposures, or psychiatric diagnoses should be considered.

After initial stimulation by hypothermia, there is progressive depression of all organ systems. The timing of the appearance of these clinical manifestations varies widely (Table 478e-2). Without knowing the core temperature, it can be difficult to interpret other vital signs. For example, tachycardia disproportionate to the core temperature suggests secondary hypothermia resulting from hypoglycemia, hypovolemia, or a toxin overdose. Because carbon dioxide production declines progressively, the respiratory rate should be low; persistent hyperventilation suggests a central nervous system (CNS) lesion or one of the organic acidoses. A markedly depressed level of consciousness in a patient with mild hypothermia raises suspicion of an overdose or CNS dysfunction due to infection or trauma.

Physical examination findings can also be altered by hypothermia. For instance, the assumption that areflexia is solely attributable to hypothermia can obscure and delay the diagnosis of a spinal cord lesion. Patients with hypothermia may be confused or combative; these symptoms abate more rapidly with rewarming than with chemical or physical restraint. A classic example of maladaptive behavior in patients with hypothermia is paradoxical undressing, which involves the inappropriate removal of clothing in response to a cold stress. The cold-induced ileus and abdominal rectus spasm can mimic or mask the presentation of an acute abdomen (Chap. 20).

TABLE 478e-2 PHYSIOLOGIC CHANGES ASSOCIATED WITH ACCIDENTAL HYPOTHERMIA

Severity	Body Temperature	Central Nervous System	Cardiovascular	Respiratory	Renal and Endocrine	Neuromuscular
Mild	35°C (95°F)– 32.2°C (90°F)	Linear depression of cerebral metabolism; amnesia; apathy; dysarthria; impaired judgment; maladaptive behavior	Tachycardia, then progressive bradycardia; cardiac cycle prolongation; vasoconstriction; increase in cardiac output and blood pressure	Tachypnea, then progressive decrease in respiratory minute volume; declining oxygen consumption; bronchorrhea; bronchospasm	Diuresis; increase in catecholamines, adrenal steroids, triiodothyronine, and thyroxine; increase in metabolism with shivering	Increased preshivering muscle tone, then fatiguing
Moderate	<32.2°C (90°F)–28°C (82.4°F)	EEG abnormalities; progressive depression of level of consciousness; pupillary dilation; paradoxical undressing; hallucinations	Progressive decrease in pulse and cardiac output; increased atrial and ventricular arrhythmias; suggestive (J-wave) ECG changes	Hypoventilation; 50% decrease in carbon dioxide production per 8°C (46°F) drop in temperature; absence of protective airway reflexes	50% increase in renal blood flow; renal autoregulation intact; impaired insulin action	Hyporeflexia; diminishing shivering-induced thermogenesis; rigidity
Severe	<28°C (<82.4°F)	Loss of cerebrovascular autoregulation; decline in cerebral blood flow; coma; loss of ocular reflexes; progressive decrease in EEG abnormalities	Progressive decrease in blood pressure, heart rate, and cardiac output; reentrant dysrhythmias; maximal risk of ventricular fibrillation; asystole	Pulmonic congestion and edema; 75% decrease in oxygen consumption; apnea	Decrease in renal blood flow that parallels decrease in cardiac output; extreme oliguria; poikilothermia; 80% decrease in basal metabolism	No motion; decreased nerve-conduction velocity; peripheral areflexia; no corneal or oculocephalic reflexes

Source: Modified from DF Danzl, RS Pozos: N Engl J Med 331:1756, 1994.

When a patient in hypothermic cardiac arrest is first discovered, cardiopulmonary resuscitation is indicated unless (1) a do-not-resuscitate status is verified, (2) obviously lethal injuries are identified, or (3) the depression of a frozen chest wall is not possible. As the resuscitation proceeds, the prognosis is grave if there is evidence of widespread cell lysis, as reflected by potassium levels >10–12 mmol/L (10–12meq/L). Other findings that may preclude continuing resuscitation include a core temperature <10–12°C (<50–54°F), a pH <6.5, and evidence of intravascular thrombosis with a fibrinogen value <0.5 g/L (<50 mg/dL). The decision to terminate resuscitation before rewarming the patient past 33°C (91°F) should be predicated on the type and severity of the precipitants of hypothermia. There are no validated prognostic indicators for recovery from hypothermia. A history of asphyxia with secondary cooling is the most important negative predictor of survival.

DIAGNOSIS AND STABILIZATION

Hypothermia is confirmed by measurement of the core temperature, preferably at two sites. Rectal probes should be placed to a depth of 15 cm and not adjacent to cold feces. A simultaneous esophageal probe should be placed 24 cm below the larynx; it may read falsely high during heated inhalation therapy. Relying solely on infrared tympanic thermography is not advisable.

After a diagnosis of hypothermia is established, cardiac monitoring should be instituted, along with attempts to limit further heat loss. If the patient is in ventricular fibrillation, it is unclear at what core temperature ventricular defibrillation (2 J/kg) should first be attempted. One attempt below 30°C is warranted. Further defibrillation attempts should be deferred until some rewarming (1°–2°C) is achieved and ventricular fibrillation is coarser. Although cardiac pacing for hypothermic bradydysrrhythmias is rarely indicated, the transthoracic technique is preferable.

Supplemental oxygenation is always warranted, since tissue oxygenation is affected adversely by the leftward shift of the oxyhemoglobin dissociation curve. Pulse oximetry may be unreliable in patients with vasoconstriction. If protective airway reflexes are absent, gentle endotracheal intubation should be performed. Adequate preoxygenation will prevent ventricular arrhythmias.

Insertion of a gastric tube prevents dilation secondary to decreased bowel motility. Indwelling bladder catheters facilitate monitoring of cold-induced diuresis. Dehydration is encountered commonly with chronic hypothermia, and most patients benefit from an intravenous or intraosseous bolus of crystalloid. Normal saline is preferable to lactated Ringer's solution, as the liver in hypothermic patients inefficiently metabolizes lactate. The placement of a pulmonary artery catheter can cause perforation of the less compliant pulmonary artery. Insertion of a central venous catheter deeply into the cold right atrium should be avoided since this procedure can precipitate arrhythmias.

Arterial blood gases should not be corrected for temperature (Chap. 66). An uncorrected pH of 7.42 and a P_{CO_2} of 40 mmHg reflect appropriate alveolar ventilation and acid-base balance at any core temperature. Acid-base imbalances should be corrected gradually, since the bicarbonate buffering system is inefficient. A common error is overzealous hyperventilation in the setting of depressed CO_2 production. When the P_{CO_2} decreases by 10 mmHg at 28°C (82°F), it doubles the pH increase of 0.08 that occurs at 37°C (99°F).

The severity of anemia may be underestimated because the hematocrit increases 2% for each 1°C drop in temperature. White blood cell sequestration and bone marrow suppression are common, potentially masking an infection. Although hypokalemia is more common in chronic hypothermia, hyperkalemia also occurs; the expected electrocardiographic changes can be obscured by hypothermia. Patients with renal insufficiency, metabolic acidoses, or rhabdomyolysis are at greatest risk for electrolyte disturbances.

Coagulopathies are common because cold inhibits the enzymatic reactions required for activation of the intrinsic cascade. In addition, thromboxane B_2 production by platelets is temperature dependent, and platelet function is impaired. The administration of platelets and fresh-frozen plasma is therefore not effective. The prothrombin or partial thromboplastin times or the international normalized ratio can be deceptively normal and contrast with the observed in vivo coagulopathy. This contradiction occurs because all coagulation tests are routinely performed at 37°C (99°F), and the enzymes are thus rewarmed.

REWARMING STRATEGIES

The key initial decision is whether to rewarm the patient passively or actively. *Passive external rewarming* simply involves covering and insulating the patient in a warm environment. With the head also covered, the rate of rewarming is usually 0.5°–2°C (1.10°–4.4°F) per hour. This technique is ideal for previously healthy patients who develop acute, mild primary accidental hypothermia. The patient must have sufficient glycogen to support endogenous thermogenesis.

The application of heat directly to the extremities of patients with chronic severe hypothermia should be avoided because it can induce peripheral vasodilation and precipitate core temperature "afterdrop," a

response characterized by a continual decline in the core temperature after removal of the patient from the cold. Truncal heat application reduces the risk of afterdrop.

Active rewarming is necessary under the following circumstances: core temperature <32°C (<90°F) (*poikilothermia*), cardiovascular instability, age extremes, CNS dysfunction, hormone insufficiency, and suspicion of secondary hypothermia. *Active external rewarming* is best accomplished with forced-air heating blankets. Other options include devices that circulate water through external heat exchange pads, radiant heat sources, and hot packs. Monitoring a patient with hypothermia in a heated tub is extremely difficult. Electric blankets should be avoided because vasoconstricted skin is easily burned.

There are numerous widely available options for *active core rewarming*. Airway rewarming with heated humidified oxygen (40°–45°C [104°–113°F]) via mask or endotracheal tube is a convenient option. Although airway rewarming provides less heat than do some other forms of active core rewarming, it eliminates respiratory heat loss and adds 1°–2°C (1.1°–4.4°F) to the overall rewarming rate. Crystalloids should be heated to 40°–42°C (104°–108°F), but the quantity of heat provided is significant only during massive volume resuscitation. The most efficient method for heating and delivering fluid or blood is with a countercurrent in-line heat exchanger. Heated irrigation of the gastrointestinal tract or bladder transfers minimal heat because of the limited available surface area. These methods should be reserved for patients in cardiac arrest and then used in combination with all available active rewarming techniques.

Closed thoracic lavage is far more efficient in severely hypothermic patients with cardiac arrest. The hemithoraxes are irrigated through two inserted large-bore thoracostomy tubes. Thoracostomy tubes should not be placed in the left chest of a spontaneously perfusing patient for purposes of rewarming. Peritoneal lavage with the dialysate at 40°–45°C (104°–113°F) efficiently transfers heat when delivered through two catheters with outflow suction. Like peritoneal dialysis, standard hemodialysis is especially useful for patients with electrolyte abnormalities, rhabdomyolysis, or toxin ingestion. Another option involves the central venous insertion of a rapid endovascular warming device.

Extracorporeal blood rewarming options **(Table 478e-3)** should be considered in severely hypothermic patients, especially those with *primary accidental hypothermia*. Cardiopulmonary bypass should be considered in nonperfusing patients without documented contraindications to resuscitation. Circulatory support may be the only effective option in patients with completely frozen extremities or those with significant tissue destruction coupled with rhabdomyolysis. There is no evidence that extremely rapid rewarming improves survival in perfusing patients. The best strategy is usually a combination of passive, truncal active, and active core rewarming techniques.

TABLE 478e-3 OPTIONS FOR EXTRACORPOREAL BLOOD REWARMING

Extracorporeal Rewarming Technique	Considerations
Continuous venovenous (CVV) rewarming	Circuit: CV catheter to CV, dual-lumen CV, or peripheral catheter
	No oxygenator/circulatory support
	Flow rates 150–400 mL/min
	ROR 2°–3°C (36°–37°F)/h
Hemodialysis	Circuit: single- or dual-vessel cannulation
	Stabilizes electrolyte or toxicologic abnormalities
	Exchange cycle volumes 200–500 mL/min
	ROR 2°–3°C (36°–37°F)/h
Continuous arteriovenous rewarming (CAVR)	Circuit: percutaneous 8.5-Fr femoral catheters
	Requires systolic blood pressure of 60 mmHg
	No perfusionist/pump/anticoagulation
	Flow rates 225–375 mL/min
	ROR 3°–4°C (37°–39°F)/h
Cardiopulmonary bypass (CPB)	Circuit: full circulatory support with pump and oxygenator
	Perfusate-temperature gradient (5°–10°C [41°–50°F])
	Flow rates 2–7 L/min (average 3–4 L/min)
	ROR up to 9.5°C (49°F)/h
Extracorporeal membrane oxygenation (ECMO)	Decreased risk of post-rewarming cardiorespiratory failure

Abbreviations: CV, central venous; ROR, rate of rewarming.

TREATMENT HYPOTHERMIA

When a patient is hypothermic, target organs and the cardiovascular system respond minimally to most medications. Generally, IV medications are withheld below 30°C (86°F). In contrast to antiarrhythmics, low-dose vasopressor medications may improve the intra-arrest rates of return of spontaneous circulation. Because of increased binding of drugs to proteins as well as impaired metabolism and excretion, either a lower dose or a longer interval between doses should be used to avoid toxicity. As an example, the administration of repeated doses of digoxin or insulin would be ineffective while the patient is hypothermic, and the residual drugs would be potentially toxic during rewarming.

Achieving a mean arterial pressure of at least 60 mmHg should be an early objective. If the hypotension does not respond to crystalloid/colloid infusion and rewarming, low-dose dopamine support (2–5 μg/kg per min) should be considered. Perfusion of the vasoconstricted cardiovascular system also may be improved with low-dose IV nitroglycerin.

Atrial arrhythmias should be monitored initially without intervention, as the ventricular response should be slow and, unless preexistent, most will convert spontaneously during rewarming. The role of prophylaxis and treatment of ventricular arrhythmias is problematic. Preexisting ventricular ectopy may be suppressed by hypothermia and reappear during rewarming. None of the class I agents has proved to be safe and efficacious. There is also insufficient evidence that the class III ventricular antiarrhythmic amiodarone is safe.

Initiating empirical therapy for adrenal insufficiency usually is not warranted unless the history suggests steroid dependence or hypoadrenalism or efforts to rewarm with standard therapy fail. The administration of parenteral levothyroxine to euthyroid patients with hypothermia, however, is potentially hazardous. Because laboratory results can be delayed and confounded by the presence of the sick euthyroid syndrome **(Chap. 405)**, historic clues or physical findings suggestive of hypothyroidism should be sought. When myxedema is the cause of hypothermia, the relaxation phase of the Achilles reflex is prolonged more than is the contraction phase.

Hypothermia obscures most of the symptoms and signs of infection, notably fever and leukocytosis. Shaking rigors from infection may be mistaken for shivering. Except in mild cases, extensive cultures and repeated physical examinations are essential. Unless an infectious source is identified, empirical antibiotic prophylaxis is most warranted in the elderly, neonates, and immunocompromised patients.

Preventive measures should be discussed with high-risk individuals, such as the elderly and people whose work frequently exposes them to extreme cold. The importance of layered clothing and headgear, adequate shelter, increased caloric intake, and the avoidance of ethanol should be emphasized, along with access to rescue services.

FROSTBITE

Peripheral cold injuries include both freezing and nonfreezing injuries to tissue. Tissue freezes quickly when in contact with thermal conductors such as metal and volatile solutions. Other predisposing factors include constrictive clothing or boots, immobility, and vasoconstrictive medications. Frostbite occurs when the tissue temperature drops below 0°C (32°F). Ice-crystal formation subsequently distorts and

destroys the cellular architecture. Once the vascular endothelium is damaged, stasis progresses rapidly to microvascular thrombosis. After the tissue thaws, there is progressive dermal ischemia. The microvasculature begins to collapse, arteriovenous shunting increases tissue pressures, and edema forms. Finally, thrombosis, ischemia, and superficial necrosis appear. The development of mummification and demarcation may take weeks to months.

CLINICAL PRESENTATION

The initial presentation of frostbite can be deceptively benign. The symptoms always include a sensory deficiency affecting light touch, pain, and temperature perception. The acral areas and distal extremities are the most common insensate areas. Some patients describe a clumsy or "chunk of wood" sensation in the extremity.

Deep frostbitten tissue can appear waxy, mottled, yellow, or violaceous-white. Favorable presenting signs include some warmth or sensation with normal color. The injury is often superficial if the subcutaneous tissue is pliable or if the dermis can be rolled over bony prominences.

Frostnip may precede frostbite. Frostnip is a nonfreezing cold injury resulting from intense vasoconstriction of exposed acral skin.

Clinically, it is most practical to classify frostbite as superficial or deep. Superficial frostbite does not entail tissue loss but rather causes only anesthesia and erythema. The appearance of vesiculation surrounded by edema and erythema implies deeper involvement (Fig. 478e-1). Hemorrhagic vesicles reflect a serious injury to the microvasculature and indicate severe frostbite. Damages in subcuticular, muscular, or osseous tissues may result in amputation.

The two most common nonfreezing peripheral cold injuries are *chilblain (pernio)* and *immersion (trench) foot*. Chilblain results from neuronal and endothelial damage induced by repetitive exposure to dry cold. Young females, particularly those with a history of Raynaud's phenomenon, are at greatest risk. Persistent vasospasticity and vasculitis can cause erythema, mild edema, and pruritus. Eventually plaques, blue nodules, and ulcerations develop. These lesions typically involve the dorsa of the hands and feet. In contrast, immersion foot results from repetitive exposure to wet cold above the freezing point. The feet initially appear cyanotic, cold, and edematous. The subsequent development of bullae is often indistinguishable from frostbite. This vesiculation rapidly progresses to ulceration and liquefaction gangrene. Patients with milder cases report hyperhidrosis, cold sensitivity, and painful ambulation for many years.

FIGURE 478e-1 Frostbite with vesiculation, surrounded by edema and erythema.

TREATMENT FROSTBITE

When frostbite accompanies hypothermia, hydration may improve vascular stasis. Frozen tissue should be thawed rapidly and completely by immersion in circulating water at 37°–40°C (99°–104°F). Rapid rewarming often produces an initial hyperemia. The early formation of large clear distal blebs is more favorable than that of smaller proximal dark hemorrhagic blebs. A common error is the premature termination of thawing, since the reestablishment of perfusion is intensely painful. Parenteral narcotics will be necessary with deep frostbite. If cyanosis persists after rewarming, the tissue compartment pressures should be monitored carefully.

Many antithrombotic and vasodilatory primary and adjunctive treatment regimens have been evaluated. The prostacyclin analogue iloprost in combination with aspirin may prove useful. There is no conclusive evidence that sympathectomy, steroids, calcium channel blockers, or hyperbaric oxygen salvages tissue.

Patients who have deep frostbite injuries with the potential for significant morbidity should be considered for intravenous or intraarterial thrombolytic therapy. Angiography or pyrophosphate scanning should help evaluate the injury and monitor the progress of tissue plasminogen activator therapy. Heparin is recommended as adjunctive therapy. Intraarterial thrombolysis may reduce the need for digital and more proximal amputations when administered within 24 h of severe injuries. A treatment protocol for frostbite is summarized in (Table 478e-4).

Unless infection develops, any decision regarding debridement or amputation should generally be deferred. Angiography or

TABLE 478e-4 TREATMENT FOR FROSTBITE

Before Thawing	During Thawing	After Thawing
Remove from environment.	Consider parenteral analgesia and ketorolac.	Gently dry and protect part; elevate; place pledgets between toes, if macerated.
Prevent partial thawing and refreezing.	Administer ibuprofen (400 mg PO).	If clear vesicles are intact, aspirate sterilely; if broken, debride and dress with antibiotic or sterile aloe vera ointment.
Stabilize core temperature and treat hypothermia.	Immerse part in 37°–40°C (99°–104°F) (thermometer-monitored) circulating water containing an antiseptic soap until distal flush (10–45 min).	Leave hemorrhagic vesicles intact to prevent desiccation and infection.
Protect frozen part—no friction or massage.	Encourage patient to gently move part.	Continue ibuprofen (400 mg PO [12 mg/kg per day] q12h).
Address medical or surgical conditions.	If pain is refractory, reduce water temperature to 35°–37°C (95°–99°F) and administer parenteral narcotics.	Consider tetanus and streptococcal prophylaxis; elevate part. Administer hydrotherapy at 37°C (99°F). Consider dextran or phenoxybenzamine or, in severe cases, thrombolysis

technetium-99 bone scan may assist in the determination of surgical margins. Magnetic resonance angiography may also demonstrate the line of demarcation earlier than does clinical demarcation.

The most common symptomatic sequelae reflect neuronal injury and persistently abnormal sympathetic tone, including paresthesias, thermal misperception, and hyperhidrosis. Delayed findings include nail deformities, cutaneous carcinomas, and epiphyseal damage in children.

Management of the chilblain syndrome is usually supportive. With refractory perniosis, alternatives include nifedipine, steroids, and limaprost, a prostaglandin E_1 analogue.

479e Heat-Related Illnesses

Daniel F. Danzl

Heat-related illnesses include a spectrum of disorders ranging from heat syncope, muscle cramps, and heat exhaustion to medical emergencies such as heatstroke. The core body temperature is normally maintained within a very narrow range. Although significant levels of hypothermia are tolerated (Chap. 478e), multiorgan dysfunction occurs rapidly at temperatures >41°–43°C. In contrast to severe hyperthermia, the far more common sign of fever reflects intact thermoregulation.

THERMOREGULATION

Humans are capable of significant heat generation. Strenuous exercise can increase heat generation twentyfold. The heat load from metabolic heat production and environmental heat absorption is balanced by a variety of heat dissipation mechanisms. These dissipation pathways are orchestrated by the central thermostat, which is located in the preoptic nucleus of the anterior hypothalamus. Efferent signals sent via the autonomic nervous system trigger cutaneous vasodilation and diaphoresis to facilitate heat loss.

Normally, the body dissipates heat into the environment via four mechanisms. The *evaporation* of skin moisture is the single most efficient mechanism of heat loss but becomes progressively ineffective as the relative humidity rises to >70%. The *radiation* of infrared electromagnetic energy directly into the surrounding environment occurs continuously. (Conversely, radiation is a major source of heat gain in hot climates.) *Conduction*— the direct transfer of heat to a cooler object—and *convection*—the loss of heat to air currents—become ineffective when the environmental temperature exceeds the skin temperature.

Factors that interfere with the evaporation of diaphoresis significantly increase the risk of heat illness. Examples include dripping of sweat off the skin, constrictive or occlusive clothing, dehydration, and excessive humidity. While air is an effective insulator, the thermal conductivity of water is 25 times greater than that of air at the same temperature. The *wet-bulb globe temperature* is a commonly used index to assess the environmental heat load. This calculation considers the ambient air temperature, the relative humidity, and the degree of radiant heat.

The regulation of this heat load is complex and involves the central nervous system (CNS), thermosensors, and thermoregulatory effectors. The central thermostat activates the effectors that produce peripheral vasodilation and sweating. The skin surface is in effect the radiator and the principal location of heat loss, since skin blood flow can increase 25–30 times over the basal rate. This dramatic increase in skin blood flow, coupled with the maintenance of peripheral vasodilation, efficiently radiates heat. At the same time, there is a compensatory vasoconstriction of the splanchnic and renal beds.

Acclimatization to heat reflects a constellation of physiologic adaptations that permit the body to lose heat more efficiently. This process often requires one to several weeks of exposure and work in a hot environment. During acclimatization, the thermoregulatory set point is altered, and this alteration affects the onset, volume, and content of diaphoresis. The threshold for the initiation of sweating is lowered, and the amount of sweat increases, with a lowered salt concentration. Sweating rates can be 1–2 L/h in acclimated individuals during heat stress. Plasma volume expansion also occurs and improves cutaneous vascular flow. The heart rate lowers, with a higher stroke volume. After the individual leaves the hot environment, improved tolerance to heat stress dissipates rapidly, the plasma volume decreases, and de-acclimatization occurs within weeks.

PREDISPOSING FACTORS AND DIFFERENTIAL DIAGNOSIS

When there is an excessive heat load, unacclimated individuals can develop a variety of heat-related illnesses. Heat waves exacerbate the mortality rate, particularly among the elderly and poor and among persons lacking adequate nutrition and access to air-conditioned environments. Secondary vascular events, including cerebrovascular accidents and myocardial infarctions, occur at least 10 times more often in conditions of extreme heat.

Exertional heat illness continues to occur when laborers, military personnel, or athletes exercise strenuously in the heat. A variety of common factors predispose to heat illness. In addition to the very young and very old, preadolescents and teenagers are at risk since they may use poor judgment when vigorously exercising in high humidity and heat. Other risk factors include obesity, poor conditioning and lack of acclimatization, and mild dehydration.

Cardiovascular inefficiency is a common feature of heat illness. Any physiologic or pharmacologic impediment to cutaneous perfusion will impair heat loss. Many patients are unaware of the heat risk associated with their medications. Anticholinergic agents impair sweating and blunt the normal cardiovascular response to heat. Phenothiazines also have anticholinergic properties that interfere with the function of the preoptic nucleus of the anterior hypothalamus due to central depletion of dopamine.

Calcium channel blockers, beta blockers, and various stimulants also inhibit sweating by reducing peripheral blood flow. To maintain the mean arterial blood pressure, increased cardiac output must be capable of compensating for progressive dehydration. A variety of stimulants and substances of abuse also increase muscle activity and heat production. Careful consideration of the differential diagnosis is important in the evaluation of a patient for a potential heat-related illness. The clinical setting may suggest other etiologies, such as malignant hyperthermia after general anesthesia or neuroleptic malignant syndrome in a patient taking certain antipsychotic medications. A variety of infectious and endocrine disorders as well as conditions with toxicologic or CNS etiologies may initially mimic heatstroke (Table 479e-1).

MINOR HEAT-EMERGENCY SYNDROMES

Heat edema is characterized by mild swelling of the hands, feet, and ankles during the first few days of significant heat exposure. The principal mechanism involves cutaneous vasodilation and pooling of interstitial fluid in response to heat stress. Heat also increases the secretion of antidiuretic hormone and aldosterone. Systemic causes of edema, including cirrhosis, nephrotic syndrome, and congestive heart failure, can usually be excluded by the history and physical examination. Heat edema generally resolves without treatment in several days. Diuretics are not effective and, in fact, predispose to volume depletion and the development of more serious heat-related illnesses.

Prickly heat (*miliaria rubra*, *lichen tropicus*) is a maculopapular, pruritic, erythematous rash that commonly occurs in clothed areas. Blockage of the sweat pores by debris from macerated stratum corneum causes inflammation in the sweat ducts. As the ducts dilate, they rupture and produce superficial vesicles. The predominant symptom is pruritus. In addition to antihistamines, chlorhexidine may provide some relief. Localized areas may benefit from 1% salicylic acid, with caution taken to avoid salicylate intoxication. Clothing should be clean and loose fitting, and activities or environments that induce diaphoresis should be avoided.

Heat syncope (exercise-associated collapse) can follow endurance exercise or can occur in the elderly. Other common clinical scenarios include prolonged standing while stationary in the heat and sudden standing after prolonged exposure to heat. Heat stress routinely causes relative volume depletion, decreased vasomotor tone, and peripheral vasodilation. The cumulative effect of this decrease in venous return is postural hypotension, especially in nonacclimated elderly individuals. Many of those affected also have comorbidities. Therefore, other cardiovascular, neurologic, and metabolic causes of syncope should be considered. After removal from the heat source, most patients will recover promptly with cooling and rehydration.

Hyperventilation tetany occurs in some individuals when exposure to heat stimulates hyperventilation, producing respiratory alkalosis, paresthesias, and carpopedal spasm. Unlike heat cramps, heat tetany causes very little muscle-compartment pain. Treatment includes

TABLE 479e-1 HEAT-RELATED ILLNESS: PREDISPOSING FACTORS AND DIFFERENTIAL DIAGNOSIS

Illness	Predisposing Factors
Cardiovascular inefficiency	Age extremes
	Beta/calcium channel blockade
	Congestive heart failure
	Dehydration
	Diuresis
	Obesity
	Poor physical fitness
Central nervous system illness	Cerebral hemorrhage
	Hypothalamic cerebrovascular accident
	Psychiatric disorders
	Status epilepticus
Impaired heat loss	Antihistamines
	Heterocyclic antidepressants
	Occlusive clothing
	Skin abnormalities
Endocrine-related illness	Diabetic ketoacidosis
	Pheochromocytoma
	Thyroid storm
Excessive heat load	Environmental conditions
	Exertion
	Fever
	Hypermetabolic state
	Lack of acclimatization
Infectious illness	Cerebral abscess
	Encephalitis
	Malaria

	Withdrawal syndromes (ethanol, hypnotics)

providing reassurance, moving the patient out of the heat, and addressing the hyperventilation.

HEAT CRAMPS

Heat cramps (exercise-associated muscle cramps) are intermittent, painful, and involuntary spasmodic contractions of skeletal muscles. They typically occur in an unacclimated individual who is at rest after vigorous exertion in a humid, hot environment. In contrast, cramps that occur in athletes during exercise last longer, are relieved by stretching and massage, and resolve spontaneously.

Of note, not all muscle cramps are related to exercise, and the differential diagnosis includes many other disorders. A variety of medications, myopathies, endocrine disorders, and sickle cell trait are other possible causes.

The typical patient with heat cramps is usually profusely diaphoretic and has been replacing fluid losses with copious water or other hypotonic fluids. Roofers, firefighters, military personnel, athletes, steel workers, and field workers are commonly affected. Other predisposing factors include insufficient sodium intake before intense activity in the heat and lack of heat acclimatization, resulting in sweat with a high salt concentration.

The precise pathogenesis of heat cramps is unclear but appears to involve a relative deficiency of sodium, potassium, and fluid at the intracellular level. Coupled with copious hypotonic fluid ingestion, large amounts of sodium in the diaphoresis cause hyponatremia and hypochloremia, resulting in muscle cramps due to calcium-dependent muscle relaxation. Total-body depletion of potassium may be observed during the period of heat acclimatization. Rhadomyolysis is very rare with routine exercise-associated muscle cramps.

Heat cramps that are not accompanied by significant dehydration can be treated with commercially available electrolyte solutions. Although the flavored electrolyte solutions are far more palatable, two 650-mg salt tablets dissolved in 1 quart of water produces a 0.1% saline solution. Individuals should avoid the ingestion of undissolved salt tablets, which are a gastric irritant and may induce vomiting.

HEAT EXHAUSTION

The physiologic hallmarks of heat exhaustion—in contrast to heatstroke—are the maintenance of thermoregulatory control and CNS function. The core temperature is usually elevated but is generally <40.5°C (<105°F). The two physiologic precipitants are water depletion and sodium depletion, which often occur in combination. Laborers, athletes, and elderly individuals exerting themselves in hot environments, without adequate fluid intake, tend to develop *water-depletion heat exhaustion*. Persons working in the heat frequently consume only two-thirds of their net water loss and are voluntarily dehydrated. In contrast, *salt-depletion heat exhaustion* occurs more slowly in unacclimated persons who have been consuming large quantities of hypotonic solutions.

Heat exhaustion is usually a diagnosis of exclusion because of the multitude of nonspecific symptoms. If any signs of heatstroke are present, rapid cooling and crystalloid resuscitation should be initiated immediately during stabilization and evaluation. Mild neurologic and gastrointestinal influenza-like symptoms are common. These symptoms may include headache, vertigo, ataxia, impaired judgment, malaise, dizziness, nausea, and muscle cramps. Orthostatic hypotension and sinus tachycardia develop frequently. More significant CNS impairment suggests heatstroke or other infectious, neurologic, or toxicologic diagnoses.

Hemoconcentration does not always develop, and rapid infusion of isotonic IV fluids should be guided by frequent electrolyte determinations and perfusion requirements. Most cases of heat exhaustion reflect mixed sodium and water depletion. Sodium-depletion heat exhaustion is characterized by hyponatremia and hypochloremia. Hepatic aminotransferases are mildly elevated in both types of heat exhaustion. Urinary sodium and chloride concentrations are usually low.

Some patients with heat exhaustion develop heatstroke after removal from the heat-stress environment. Aggressive cooling of nonresponders is indicated until their core temperature is 39°C (102.2°F). Except in mild cases, free water deficits should be replaced slowly over 24–48 h to avoid a decrease of serum osmolality by >2 mOsm/h.

The disposition of younger, previously healthy heat-exhaustion patients who have no major laboratory abnormalities may include hospital observation and discharge after IV rehydration. Older patients with comorbidities (including cardiovascular disease) or predisposing factors often require inpatient fluid and electrolyte replacement, monitoring, and reassessment.

HEATSTROKE

The clinical manifestations of heatstroke reflect a total loss of thermoregulatory function. Typical vital-sign abnormalities include tachypnea, various tachycardias, hypotension, and a widened pulse pressure. Although there is no single specific diagnostic test, the historical and physical triad of exposure to a heat stress, CNS dysfunction, and a core temperature >40.5°C helps establish the preliminary diagnosis.

TABLE 479e-2 TYPICAL MANIFESTATIONS OF HEATSTROKE

Classic	Exertional
Older patient	Younger patient
Predisposing health factors/medications	Healthy condition
Epidemiology (heat waves)	Sporadic cases
Sedentary	Exercising
Anhidrosis (possible)	Diaphoresis (common)
Central nervous system dysfunction	Myocardial/hepatic injury
Oliguria	Acute renal failure
Coagulopathy (mild)	Disseminated intravascular coagulation
Mild lactic acidosis	Marked lactic acidosis
Mild creatine kinase elevation	Rhabdomyolysis
Normoglycemia/calcemia	Hypoglycemia/calcemia
Normokalemia	Hyperkalemia

The definitive diagnosis should be reserved until the other potential causes of hyperthermia are excluded. Many of the usual laboratory abnormalities seen with heatstroke overlap with other conditions. If the patient's mental status does not improve with cooling, toxicologic screening may be indicated, and cranial CT and spinal fluid analysis can be considered.

The premonitory clinical characteristics may be nonspecific and include weakness, dizziness, disorientation, ataxia, and gastrointestinal or psychiatric symptoms. These prodromal symptoms often resemble heat exhaustion. The sudden onset of heatstroke occurs when the maintenance of adequate perfusion requires peripheral vasoconstriction to stabilize the mean arterial blood pressure. As a result, the cutaneous radiation of heat ceases. At this juncture, the core temperature rises dramatically. Since many patients with heatstroke also meet the criteria for systemic inflammatory response syndrome and have a broad differential diagnosis, rapid cooling is essential during the extensive diagnostic evaluation (Table 479e-1).

There are two forms of heatstroke with significantly different manifestations (Table 479e-2). Classic (epidemic) heatstroke (CHS) usually occurs during long periods of high ambient temperature and humidity, as during summer heat waves. Patients with CHS commonly have chronic diseases that predispose to heat-related illness, and they may have limited access to oral fluids. Heat dissipation mechanisms are overwhelmed by both endogenous heat production and exogenous heat stress. Patients with CHS are often compliant with prescribed medications that can impair tolerance to a heat stress. In many of these dehydrated CHS patients, sweating has ceased and the skin is hot and dry. If cooling is delayed, severe hepatic dysfunction, renal failure, disseminated intravascular coagulation, and fulminant multisystem organ failure may occur. Hepatocytes are very heat sensitive. On presentation, the serum level of aspartate aminotransferase (AST) is routinely elevated. Eventually, levels of both AST and alanine aminotransferase (ALT) often increase to >100 times the normal values. Coagulation studies commonly demonstrate decreased platelets, fibrinogen, and prothrombin. Most patients with CHS require cautious crystalloid resuscitation, electrolyte monitoring, and—in certain refractory cases—consideration of central venous pressure (CVP) measurements. Hypernatremia is secondary to dehydration in CHS. Many patients exhibit significant stress leukocytosis, even in the absence of infection.

Patients with exertional heatstroke (EHS), in contrast to those with CHS, are often young and previously healthy, and their diagnosis is usually more obvious from the history. Athletes, laborers, and military recruits are common victims. Unlike those with CHS, many EHS patients present profusely diaphoretic despite significant dehydration. As a result of muscular exertion, rhabdomyolysis and acute renal failure are more common in EHS. Studies to detect rhabdomyolysis and its complications, including hypocalcemia and hyperphosphatemia, should be considered. Hyponatremia, hypoglycemia, and coagulopathies are frequent findings. Elevated creatine kinase and lactate dehydrogenase levels also suggest EHS. Oliguria is a common finding. Renal failure can result from direct thermal injury, untreated rhabdomyolysis, or volume depletion. Common urinalysis findings include microscopic hematuria, myoglobinuria, and granular or red cell casts.

With both CHS and EHS, heat-related reversible increases in cardiac biomarker levels are often present. Heatstroke often causes thermal cardiomyopathy. As a result, the CVP may be elevated despite significant dehydration. In addition, the patient often presents with potentially deceptive noncardiogenic pulmonary edema and basilar rales despite being significantly hypovolemic. The electrocardiogram commonly displays a variety of tachyarrhythmias, nonspecific ST-T wave changes, and heat-related ischemia or infarction. Rapid cooling—not the administration of antiarrhythmic medications—is essential.

Above 42°C (107.6° F), heat can rapidly produce direct cellular injury. Thermosensitive enzymes become nonfunctional, and eventually there is irreversible uncoupling of oxidative phosphorylation. The production of heat-shock proteins increases, and cytokines mediate a systemic inflammatory response. The vascular endothelium is also damaged, and this injury activates the coagulation cascade. Significant shunting away from the splanchnic circulation produces gastrointestinal ischemia. Endotoxins further impair normal thermoregulation. As a result, if cooling is delayed, severe hepatic dysfunction, permanent renal failure, disseminated intravascular coagulation, and fulminant multisystem organ failure may occur.

COOLING STRATEGIES

Before cooling is initiated, endotracheal intubation, CVP determination, and continuous core-temperature monitoring should be considered. Hypoglycemia is a frequent finding and can be addressed by glucose infusion. Since peripheral vasoconstriction delays heat dissipation, repeated administration of discrete boluses of isotonic crystalloid for hypotension is preferable to the administration of α-adrenergic agonists.

Evaporative cooling is usually the most practical and effective technique. Rapid cooling is essential in both CHS and EHS, and an immediate improvement in vital signs and mental status may prove valuable for diagnostic purposes. Cool water (15°C [60° F]) is sprayed on the exposed skin while fans direct continuous airflow over the moistened skin. Cold packs applied to the axillae and groin are a useful cooling adjunct. If cardiac electrodes will not adhere, they can be applied to the patient's back. To avoid "overshoot hypothermia," active cooling should be terminated at ~38°–39°C (100.4°–102.2°F).

Immersion cooling in cold water is an alternative option in EHS but induces peripheral vasoconstriction and intense shivering. This technique presents significant monitoring and resuscitation challenges in most clinical settings. The safety of immersion cooling is best established for young, previously healthy patients with EHS (but not for those with CHS).

Cooling with commercially available cooling blankets should not be the sole technique used, since the rate of cooling is far too slow. Other methods are less efficacious and rarely indicated, such as IV infusion of cold fluids and cold irrigation of the bladder or gastrointestinal tract. Cold thoracic and peritoneal lavage are efficient maneuvers but are invasive and rarely necessary. Cardiopulmonary bypass provides fast and effective cooling but is labor intensive and is rarely available on a stat basis.

RESUSCITATION

Aspiration and seizures commonly occur in heatstroke, and endotracheal intubation is usually necessary. The metabolic demands are high, and supplemental oxygenation is essential due to hypoxemia induced by thermal stress and pulmonary dysfunction. Pneumonitis, pulmonary infarction, hemorrhage, edema, and acute respiratory distress syndrome occur frequently in heatstroke patients.

The circulatory fluid requirements, particularly in CHS, may be deceptively modest. Aggressive cooling and modest volume repletion usually elevate the CVP to 12–14 mmHg. The reading, however,

may be deceptive. Many patients present with a thermally induced hyperdynamic circulation accompanied by a high cardiac index, low peripheral vascular resistance, and an elevated CVP caused by right-sided heart failure. Rarely, wedge pressures measured via a pulmonary artery catheter may be necessary to guide resuscitation. In contrast, most patients with EHS require far more zealous isotonic crystalloid resuscitation.

The hypotension that is initially common among patients with heatstroke results from both dehydration and high-output cardiac failure caused by peripheral vasodilation. Inotropes causing α-adrenergic stimulation (e.g., norepinephrine) can impede cooling by causing significant vasoconstriction. Vasoactive catecholamines such as dopamine or dobutamine may be necessary if the cardiac output remains depressed despite an elevated CVP, particularly in patients with a hyperdynamic circulation.

A wide variety of tachyarrhythmias are routinely observed on presentation and usually resolve during cooling. The administration of atrial or ventricular antiarrhythmic medications is rarely indicated during cooling. Anticholinergic medications (including atropine) that inhibit sweating should not be given, and electrical cardioversion of the hyperthermic myocardium should be avoided except when there is ventricular fibrillation.

Significant shivering, discomfort, or extreme agitation is preferably mitigated with short-acting benzodiazepines, which are ideal due to their renal clearance. On the other hand, chlorpromazine may lower the seizure threshold, has anticholinergic properties, and can exacerbate the hypotension or cause neuroleptic malignant syndrome. Because of likely hepatic dysfunction, barbiturates should be avoided and seizures should be treated with benzodiazepines.

Coagulopathies more commonly occur after the first day of illness. After cooling, the patient should be monitored for laboratory signs of disseminated intravascular coagulation, and replacement therapy with fresh-frozen plasma and platelets should be considered.

There is no therapeutic role for antipyretics in the control of environmentally induced hyperthermia; these drugs block the actions of pyrogens at hypothalamic receptor sites. Salicylates can further uncouple oxidative phosphorylation in heatstroke and exacerbate coagulopathies. Acetaminophen may further stress hepatic function. The safety and efficacy of other medications, including dantrolene and aminocaproic acid, are not established.

DISPOSITION

Most patients with minor heat-emergency syndromes (including heat edema, heat syncope, and heat cramps) require only stabilization and treatment with outpatient follow-up. Although there are no decision rules to guide disposition choices in heat exhaustion, many of these patients have multiple predisposing factors and comorbidities that will require prolonged observation or hospital admission.

Essentially all patients with actual heatstroke require admission to a monitored setting, and most require intensive care. Many of these patients also require prolonged tracheal intubation, invasive hemodynamic monitoring, and support for various degrees of multiorgan dysfunction syndrome. The prognosis worsens if the initial core temperature exceeds 42°C (107.6°F) or if there was a prolonged period during which the core temperature exceeded this level. Other features of a negative prognosis include acute renal failure, massively elevated liver enzymes, and significant hyperkalemia. As expected, the number of dysfunctional organ systems also correlates directly with mortality risk.

APPENDIX: Laboratory Values of Clinical Importance

Alexander Kratz, Michael A. Pesce, Robert C. Basner, Andrew J. Einstein

This Appendix contains tables of reference values for common laboratory tests. A variety of factors can influence reference values. Such variables include the population studied, the duration and means of specimen transport, laboratory methods and instrumentation, and even the type of container used for the collection of the specimen. The reference or "normal" ranges given in this appendix may therefore not be appropriate for all laboratories, and these values should only be used as general guidelines. Whenever possible, reference values provided by the laboratory performing the testing should be used in the interpretation of laboratory data. Values supplied in this Appendix reflect typical reference ranges in nonpregnant adults. Pediatric reference ranges and values in pregnant patients may vary significantly from the data presented in the Appendix.

In preparing the Appendix, the authors have taken into account the fact that the system of international units (SI, système international d'unités) is used in most countries and in some medical journals. However, clinical laboratories may continue to report values in "traditional" or conventional units. Therefore, both systems are provided in the Appendix. The dual system is also used in the text except for those instances in which the numbers remain the same and only the terminology is changed (mmol/L for meq/L or IU/L for mIU/mL), when only the SI units are given.

TABLE 1 HEMATOLOGY AND COAGULATION

Analyte	Specimen	SI Units	Conventional Units
Activated clotting time	WB	70–180 s	70–180 s
Activated protein C resistance (factor V Leiden)	P	Not applicable	Ratio >2.1
ADAMTS13 activity	P	≥0.67	≥67%
ADAMTS13 inhibitor activity	P	Not applicable	≤0.4 U
ADAMTS13 antibody	P	Not applicable	≤18 U

Bile acids	S		
Cholic acid		0–1.9 µmol/L	0–1.9 µmol/L
Chenodeoxycholic acid		0–3.4 µmol/L	0–3.4 µmol/L
Deoxycholic acid		0–2.5 µmol/L	0–2.5 µmol/L
Ursodeoxycholic acid		0–1.0 µmol/L	0–1.0 µmol/L
Total		0–7.0 µmol/L	0–7.0 µmol/L
Bilirubin	S		
Total		5.1–22 µmol/L	0.3–1.3 mg/dL
Direct		1.7–6.8 µmol/L	0.1–0.4 mg/dL
Indirect		3.4–15.2 µmol/L	0.2–0.9 mg/dL
C peptide	S	0.27–1.19 nmol/L	0.8–3.5 ng/mL
C1-esterase-inhibitor protein	S	210–390 mg/L	21–39 mg/dL
CA 125	S	<35 kU/L	<35 U/mL
CA 19-9	S	<37 kU/L	<37 U/mL
CA 15-3	S	<33 kU/L	<33 U/mL
CA 27-29	S	0–40 kU/L	0–40 U/mL
Calcitonin	S		
Male		0–7.5 ng/L	0–7.5 pg/mL
Female		0–5.1 ng/L	0–5.1 pg/mL
Calcium	S	2.2–2.6 mmol/L	8.7–10.2 mg/dL
Calcium, ionized	WB	1.12–1.32 mmol/L	4.5–5.3 mg/dL
Carbon dioxide content (TCO_2)	P (sea level)	22–30 mmol/L	22–30 meq/L
Carboxyhemoglobin (carbon monoxide content)	WB		
Nonsmokers (in a nonsmoking environment)		0.0–0.025	0–2.5% of total hemoglobin (Hgb) value
Smokers		0.04–0.09	4–9% of total Hgb value
Loss of consciousness and death		>0.50	>50% of total Hgb value
Carcinoembryonic antigen (CEA)	S		
Nonsmokers		0.0–3.0 µg/L	0.0–3.0 ng/mL
Smokers		0.0–5.0 µg/L	0.0–5.0 ng/mL
Ceruloplasmin	S	250–630 mg/L	25–63 mg/dL
Chloride	S	102–109 mmol/L	102–109 meq/L
Cholesterol (LCL, Total, HDL): Ranges depend on individual patient factors; see 2013 ACC/AHA Guideline on the Treatment of Blood Cholesterol			
Cholinesterase	S	5–12 kU/L	5–12 U/mL
Chromogranin A	S	0–95 µg/L	0–95 ng/mL
Complement	S		
C3		0.83–1.77 g/L	83–177 mg/dL
C4		0.16–0.47 g/L	16–47 mg/dL
Complement total		60–144 CAE units	60–144 CAE units
Cortisol			
Fasting, 8 A.M.–12 noon	S	138–690 nmol/L	5–25 µg/dL
12 noon–8 P.M.		138–414 nmol/L	5–15 µg/dL
8 P.M.–8 A.M.		0–276 nmol/L	0–10 µg/dL
C-reactive protein	S	<10 mg/L	<10 mg/L
C-reactive protein, high sensitivity	S	Cardiac risk Low: <1.0 mg/L Average: 1.0–3.0 mg/L High: >3.0 mg/L	Cardiac risk Low: <1.0 mg/L Average: 1.0–3.0 mg/L High: >3.0 mg/L

TABLE 2 CLINICAL CHEMISTRY AND IMMUNOLOGY (*CONTINUED*)

Analyte	Specimen	SI Units	Conventional Units
Creatine kinase (total)	S		
Females		0.66–4.0 µkat/L	39–238 U/L
Males		0.87–5.0 µkat/L	51–294 U/L
Creatine kinase-MB	S		
Mass		0.0–5.5 µg/L	0.0–5.5 ng/mL
Fraction of total activity (by electrophoresis)		0–0.04	0–4.0%
Creatinine	S		
Female		44–80 µmol/L	0.5–0.9 mg/dL
Male		53–106 µmol/L	0.6–1.2 mg/dL
Cryoglobulins	S	Not applicable	None detected
Cyclic citrullinated peptide (CCP) antibody (IgG)	S	Negative: <20 Units	Negative: <20 Units
		Weak positive: 20–39 Units	Weak positive: 20–39 Units
		Moderate positive: 40–59 Units	Moderate positive: 40–59 Units
		Strong positive: ≥60 Units	Strong positive: ≥60 Units
Cystatin C	S	0.5–1.0 mg/L	0.5–1.0 mg/L
Deamidated gliadin peptide (DGP) antibody, IgA	S		
Negative		≤19 Units	≤19 Units
Weak positive		20–30 Units	20–30 Units
Positive		≥31 Units	≥31 Units
Deamidated gliadin peptide (DGP) antibody, IgG	S		
Negative		≤19 Units	≤19 Units
Weak positive		20–30 Units	20–30 Units
Positive		≥31 Units	≥31 Units
Dehydroepiandrosterone (DHEA) (adult)			
Male	S	6.2–43.4 nmol/L	180–1250 ng/dL
Female		4.5–34.0 nmol/L	130–980 ng/dL
Dehydroepiandrosterone (DHEA) sulfate	S		
Male (adult)		100–6190 µg/L	10–619 µg/dL
Female (adult, premenopausal)		120–5350 µg/L	12–535 µg/dL
Female (adult, postmenopausal)		300–2600 µg/L	30–260 µg/dL
11-Deoxycortisol (adult) (compound S)	S	0.34–4.56 nmol/L	12–158 ng/dL
Dihydrotestosterone			
Male	S, P	1.03–2.92 nmol/L	30–85 ng/dL
Female		0.14–0.76 nmol/L	4–22 ng/dL
Dopamine	P	0–130 pmol/L	0–20 pg/mL
Endomysial antibody, IgA	S	<1:10	<1:10
Endomysial antibody, IgG	S	<1:10	<1:10
Epinephrine	P		
Supine (30 min)		<273 pmol/L	<50 pg/mL
Sitting		<328 pmol/L	<60 pg/mL
Standing (30 min)		<491pmol/L	<90 pg/mL
Erythropoietin	S	4–27 U/L	4–27 U/L
Estradiol	S, P		
Female			
Menstruating:			
Follicular phase		74–532 pmol/L	<20–145 pg/mL
Midcycle peak		411–1626 pmol/L	112–443 pg/mL
Luteal phase		74–885 pmol/L	<20–241 pg/mL
Postmenopausal		217 pmol/L	<59 pg/mL
Male		74 pmol/L	<20 pg/mL
Estrone	S, P		
Female			
Menstruating:			
Follicular phase		<555 pmol/L	<150 pg/mL
Luteal phase		<740 pmol/L	<200 pg/mL
Postmenopausal		11–118 pmol/L	3–32 pg/mL
Male		33–133 pmol/L	9–36 pg/mL

(*Continued*)

TABLE 2 CLINICAL CHEMISTRY AND IMMUNOLOGY (*CONTINUED*)

Analyte	Specimen	SI Units	Conventional Units
Fatty acids, free (nonesterified)	P	0.1–0.6 mmol/L	2.8–16.8 mg/dL
Ferritin	S		
Female		10–150 µg/L	10–150 ng/mL
Male		29–248 µg/L	29–248 ng/mL
Follicle-stimulating hormone (FSH)	S, P		
Female			
Menstruating			
Follicular phase		3.0–20.0 IU/L	3.0–20.0 mIU/mL
Ovulatory phase		9.0–26.0 IU/L	9.0–26.0 mIU/mL
Luteal phase		1.0–12.0 IU/L	1.0–12.0 mIU/mL
Postmenopausal		18.0–153.0 IU/L	18.0–153.0 mIU/mL
Male		1.0–12.0 IU/L	1.0–12.0 mIU/mL
Fructosamine	S	<285 µmol/L	<285 µmol/L
Galectin-3	S		
Low risk		≤17.8 µg/L	≤17.8 ng/mL
Intermediate risk		17.9–25.9 µg/L	17.9–25.9 ng/mL
Higher risk		>25.9 µg/L	>25.9 ng/mL
Gamma glutamyltransferase	S	0.15–0.99 µkat/L	9–58 U/L
Gastrin	S	<100 ng/L	<100 pg/mL
Glucagon	P	40–130 ng/L	40–130 pg/mL
Glucose	WB	3.6–5.3 mmol/L	65–95 mg/dL
Glucose (fasting)	P		
Normal		4.2–5.6 mmol/L	75–100 mg/dL
Increased risk for diabetes		5.6–6.9 mmol/L	100–125 mg/dL
Diabetes mellitus		Fasting ≥7.0 mmol/L	Fasting ≥126 mg/dL
		A 2-h level of ≥11.1 mmol/L during an oral glucose tolerance test	A 2-h level of ≥200 mg/dL during an oral glucose tolerance test
		A random glucose level of ≥11.1 mmol/L in patients with symptoms of hyperglycemia	A random glucose level of ≥200 mg/dL in patients with symptoms of hyperglycemia
Growth hormone	S	0–5 µg/L	0–5 ng/mL
Hemoglobin A_{1c}	WB	0.04–0.06 Hgb fraction	4.0–5.6%
Prediabetes		0.057–0.064 Hgb fraction	5.7–6.4%
Diabetes mellitus		A hemoglobin A_{1c} level of ≥0.065 Hgb fraction as suggested by the American Diabetes Association	A hemoglobin A_{1c} level of ≥6.5% as suggested by the American Diabetes Association
Hemoglobin A_{1c} with estimated average glucose (eAG)	WB	eAg mmoL/L = 1.59 × HbA_{1c} – 2.59	eAg (mg/dL) = 28.7 × HbA_{1c} – 46.7
Homocysteine	P	4.4–10.8 µmol/L	4.4–10.8 µmol/L
Human chorionic gonadotropin (HCG)	S		
Nonpregnant female		<5 IU/L	<5 mIU/mL
1–2 weeks postconception		9–130 IU/L	9–130 mIU/mL
2–3 weeks postconception		75–2600 IU/L	75–2600 mIU/mL
3–4 weeks postconception		850–20,800 IU/L	850–20,800 mIU/mL
4–5 weeks postconception		4000–100,200 IU/L	4000–100,200 mIU/mL
5–10 weeks postconception		11,500–289,000 IU/L	11,500–289,000 mIU/mL
10–14 weeks postconception		18,300–137,000 IU/L	18,300–137,000 mIU/mL
Second trimester		1400–53,000 IU/L	1400–53,000 mIU/mL
Third trimester		940–60,000 IU/L	940–60,000 mIU/mL
Human epididymis protein 4 (HE-4)	S	0–150 pmol/L	0–150 pmol/L
β-Hydroxybutyrate	P	60–170 µmol/L	0.6–1.8 mg/dL
17-Hydroxyprogesterone (adult)	S		
Male		<4.17 nmol/L	<139 ng/dL
Female			
Follicular phase		0.45–2.1 nmol/L	15–70 ng/dL
Luteal phase		1.05–8.7 nmol/L	35–290 ng/dL
Immunofixation	S	Not applicable	No bands detected

(*Continued*)

Analyte	Specimen	SI Units	Conventional Units
Immunoglobulin, quantitation (adult)			
IgA	S	0.70–3.50 g/L	70–350 mg/dL
IgD	S	0–140 mg/L	0–14 mg/dL
IgE	S	1–87 KIU/L	1–87 IU/mL
IgG	S	7.0–17.0 g/L	700–1700 mg/dL
IgG_1	S	2.7–17.4 g/L	270–1740 mg/dL
IgG_2	S	0.3–6.3 g/L	30–630 mg/dL
IgG_3	S	0.13–3.2 g/L	13–320 mg/dL
IgG_4	S	0.11–6.2 g/L	11–620 mg/dL
IgM	S	0.50–3.0 g/L	50–300 mg/dL
Inhibin A	S		
Males		≤2.0 ng/L	≤2.0 pg/mL
Females			
Early follicular phase		1.8–17.3 ng/L	1.8–17.3 pg/mL
Mid follicular phase		3.5–31.7 ng/L	3.5–17.3 pg/mL
Late follicular phase		9.8–90.3 ng/L	9.8–90.3 pg/mL
Midcycle		16.9–91.8 ng/L	16.9–91.8 pg/mL
Early luteal phase		16.1–97.5 ng/L	16.1–97.5 pg/mL
Mid luteal phase		3.9–87.7 ng/L	3.9–87.7 pg/mL
Late luteal phase		2.7–47.1 ng/L	2.7–47.1 pg/mL
Postmenopausal		<1.0–2.1 ng/L	<1.0–2.1 pg/mL
Insulin	S, P	14.35–143.5 pmol/L	2–20 µU/mL
Iron	S	7–25 µmol/L	41–141 µg/dL
Iron-binding capacity	S	45–73 µmol/L	251–406 µg/dL
Iron-binding capacity saturation	S	0.16–0.35	16–35%
Ischemia modified albumin	S	<85 KU/L	<85 U/mL
Joint fluid crystal	JF	Not applicable	No crystals seen
Joint fluid mucin	JF	Not applicable	Only type I mucin present
Ketone (acetone)	S	Negative	Negative
Lactate	P, arterial	0.5–1.6 mmol/L	4.5–14.4 mg/dL
	P, venous	0.5–2.2 mmol/L	4.5–19.8 mg/dL
Lactate dehydrogenase	S	2.0–3.8 µkat/L	115–221 U/L
Lamellar body count	AMF		
Immature		<15,000/µL	<15,000/µL
Indeterminate		15,000–50,000/µL	15,000-50,000/µL
Mature		>50,000/µL	>50,000/µL
Lecithin/sphingomyelin (L/S) ratio	AMF		
Immature		≤1.5	≤1.5
Transitional		1.5–1.9	1.5–1.9
Mature		2.0–2.5 or greater	2.0–2.5 or greater
Lipase	S	0.51–0.73 µkat/L	3–43 U/L
Lipoprotein (a)	S	0–300 mg/L	0–30 mg/dL
Lipoprotein associated phospholipase A2	S, P	0–234 µg/L	0-234 ng/mL
Luteinizing hormone (LH)	S, P		
Female			
Menstruating			
Follicular phase		2.0–15.0 U/L	2.0–15.0 mIU/mL
Ovulatory phase		22.0–105.0 U/L	22.0–105.0 mIU/mL
Luteal phase		0.6–19.0 U/L	0.6–19.0 mIU/mL
Postmenopausal		16.0–64.0 U/L	16.0–64.0 mIU/mL
Male		2.0–12.0 U/L	2.0–12.0 mIU/mL
Magnesium	S	0.62–0.95 mmol/L	1.5–2.3 mg/dL
Metanephrine	P	<0.5 nmol/L	<100 pg/mL
Methemoglobin	WB	0.0–0.01	0–1% of total Hgb value

TABLE 3 TOXICOLOGY AND THERAPEUTIC DRUG MONITORING

	Therapeutic Range		Toxic Level	
Drug	SI Units	Conventional Units	SI Units	Conventional Units
Acetaminophen	66–199 µmol/L	10–30 µg/mL	>1320 µmol/L	>200 µg/mL
Amikacin				
Peak	34–51 µmol/L	20–30 µg/mL	>60 µmol/L	>35 µg/mL
Trough	0–17 µmol/L	0–10 µg/mL	>17 µmol/L	>10 µg/mL
Amitriptyline/nortriptyline (total drug)	430–900 nmol/L	120–250 ng/mL	>1800 nmol/L	>500 ng/mL
Amphetamine	150–220 nmol/L	20–30 ng/mL	>1500 nmol/L	>200 ng/mL
Bromide	9.4–18.7 mmol/L	75–150 mg/dL	>18.8 mmol/L	>150 mg/dL
Mild toxicity			6.4–18.8 mmol/L	51–150 mg/dL
Severe toxicity			>18.8 mmol/L	>150 mg/dL
Lethal			>37.5 mmol/L	>300 mg/dL
Caffeine	25.8–103 µmol/L	5–20 µg/ml	>206 µmol/L	>40 µg/mL
Carbamazepine	17–42 µmol/L	4–10 µg/mL	> 85 µmol/L	>20 µg/mL
Chloramphenicol				
Peak	31–62 µmol/L	10–20 µg/mL	>77 µmol/L	>25 µg/mL
Trough	15–31 µmol/L	5–10 µg/mL	>46 µmol/L	>15 µg/mL
Chlordiazepoxide	1.7–10 µmol/L	0.5–3.0 µg/mL	>17 µmol/L	>5.0 µg/mL
Clonazepam	32–240 nmol/L	10–75 ng/mL	>320 nmol/L	>100 ng/mL
Clozapine	0.6–2.1 µmol/L	200–700 ng/mL	>3.7 µmol/L	>1200 ng/mL
Cocaine			>3.3 µmol/L	>1.0 µg/mL
Codeine	43–110 nmol/mL	13–33 ng/mL	>3700 nmol/mL	>1100 ng/mL (lethal)
Cyclosporine				
Renal transplant				
0–6 months	208–312 nmol/L	250–375 ng/mL	>312 nmol/L	>375 ng/mL
6–12 months after transplant	166–250 nmol/L	200–300 ng/mL	>250 nmol/L	>300 ng/mL
>12 months	83–125 nmol/L	100–150 ng/mL	>125 nmol/L	>150 ng/mL
Cardiac transplant				
0–6 months	208–291 nmol/L	250–350 ng/mL	>291 nmol/L	>350 ng/mL
6–12 months after transplant	125–208 nmol/L	150–250 ng/mL	>208 nmol/L	>250 ng/mL
>12 months	83–125 nmol/L	100–150 ng/mL	>125 nmol/L	150 ng/mL
Lung transplant				
0–6 months	250–374 nmol/L	300–450 ng/mL	>374 nmol/L	>450 ng/mL
Liver transplant				
Initiation	208–291 nmol/L	250–350 ng/mL	>291 nmol/L	>350 ng/mL
Maintenance	83–166 nmol/L	100–200 ng/mL	>166 nmol/L	>200 ng/mL
Desipramine	375–1130 nmol/L	100–300 ng/mL	>1880 nmol/L	>500 ng/mL
Diazepam (and metabolite)				
Diazepam	0.7 –3.5 µmol/L	0.2–1.0 µg/mL	>7.0 µmol/L	>2.0 µg/mL
Nordiazepam	0.4– 6.6 µmol/L	0.1–1.8 µg/mL	>9.2 µmol/L	>2.5 µg/mL
Digoxin	0.64–1.6 nmol/L	0.5–1.2 ng/mL	>3.1 nmol/L	>2.4 ng/mL
Disopyramide	5.3–14.7 µmol/L	2–5 µg/mL	>20.6 µmol/L	>7 µg/mL
Doxepin and nordoxepin				
Doxepin	0.36–0.98 µmol/L	101–274 ng/mL	>1.8 µmol/L	>503 ng/mL
Nordoxepin	0.38–1.04 µmol/L	106–291 ng/mL	>1.9 µmol/L	>531 ng/mL

Vitamin B_6	P	20–121 nmol/L	5–30 ng/mL
Vitamin B_{12}	S	206–735 pmol/L	279–996 pg/mL
Vitamin C (ascorbic acid)	S	23–57 µmol/L	0.4–1.0 mg/dL
Vitamin D 1,25-dihydroxy, total	S, P	36–180 pmol/L	15–75 pg/mL
Vitamin D 25-hydroxy, total	P	75–250 nmol/L	30–100 ng/mL
Vitamin E	S	12–42 µmol/L	5–18 µg/mL
Vitamin K	S	0.29–2.64 nmol/L	0.13–1.19 ng/mL
Zinc	S	11.5–18.4 µmol/L	75–120 µg/dL

Abbreviations: P, plasma; RC, red cells; S, serum; WB, whole blood.

TABLE 5 CEREBROSPINAL FLUID[a]

Constituent	Reference Range	
	SI Units	Conventional Units
Osmolarity	292–297 mmol/kg water	292–297 mOsm/L
Electrolytes		
Sodium	137–145 mmol/L	137–145 meq/L
Potassium	2.7–3.9 mmol/L	2.7–3.9 meq/L
Calcium	1.0–1.5 mmol/L	2.1–3.0 meq/L
Magnesium	1.0–1.2 mmol/L	2.0–2.5 meq/L
Chloride	116–122 mmol/L	116–122 meq/L
CO_2 content	20–24 mmol/L	20–24 meq/L
P_{CO_2}	6–7 kPa	45–49 mmHg
pH	7.31–7.34	
Glucose	2.22–3.89 mmol/L	40–70 mg/dL
Lactate	1–2 mmol/L	10–20 mg/dL
Total protein:		
Lumbar	0.15–0.5 g/L	15–50 mg/dL
Cisternal	0.15–0.25 g/L	15–25 mg/dL
Ventricular	0.06–0.15 g/L	6–15 mg/dL
Albumin	0.066–0.442 g/L	6.6–44.2 mg/dL
IgG	0.009–0.057 g/L	0.9–5.7 mg/dL
IgG index[b]	0.29–0.59	
Oligoclonal bands (OGB)	<2 bands not present in matched serum sample	
Ammonia	15–47 µmol/L	25–80 µg/dL
Creatinine	44–168 µmol/L	0.5–1.9 mg/dL
Myelin basic protein	<4 µg/L	
Cerebrospinal fluid pressure		50–180 mmH_2O
Cerebrospinal fluid volume (adult)	~150 mL	
Red blood cells	0	0
Leukocytes		
Total	0–5 mononuclear cells per µL	
Differential		
Lymphocytes	60–70%	
Monocytes	30–50%	
Neutrophils	None	

[a]Since cerebrospinal fluid (CSF) concentrations are equilibrium values, measurements of the same parameters in blood plasma obtained at the same time are recommended. However, there is a time lag in attainment of equilibrium, and cerebrospinal levels of plasma constituents that can fluctuate rapidly (such as plasma glucose) may not achieve stable values until after a significant lag phase. [b]IgG index = CSF IgG (mg/dL) × serum albumin (g/dL)/serum IgG (g/dL) × CSF albumin (mg/dL).

TABLE 6 URINE ANALYSIS AND RENAL FUNCTION TESTS

	Reference Range	
	SI Units	**Conventional Units**
Acidity, titratable	20–40 mmol/d	20–40 meq/d
Aldosterone	Normal diet: 6–25 µg/d	Normal diet: 6–25 µg/d
	Low-salt diet: 17–44 µg/d	Low-salt diet: 17–44 µg/d
	High-salt diet: 0–6 µg/d	High-salt diet: 0–6 µg/d
Aluminum	0.19–1.11 µmol/L	5–30 µg/L
Ammonia	30–50 mmol/d	30–50 meq/d
Amylase		4–400 U/L
Amylase/creatinine clearance ratio ($[Cl_{am}/Cl_{cr}] \times 100$)	1–5	1–5
Arsenic	0.07–0.67 µmol/d	5–50 µg/d
Bence Jones protein, urine, qualitative	Not applicable	None detected
Bence Jones protein, urine, quantitative		
Free kappa	1.4–24.2 mg/L	0.14–2.42 mg/dL
Free lambda	0.2–6.7 mg/L	0.02–0.67 mg/dL
K/L ratio	2.04–10.37	2.04–10.37
Calcium (10 meq/d or 200 mg/d dietary calcium)	<7.5 mmol/d	<300 mg/d
Chloride	140–250 mmol/d	140–250 mmol/d
Citrate	320–1240 mg/d	320–1240 mg/d
Copper	<0.95 µmol/d	<60 µg/d
Coproporphyrins (types I and III)	0–20 µmol/mol creatinine	0–20 µmol/mol creatinine
Cortisol, free	55–193 nmol/d	20–70 µg/d
Creatine, as creatinine		
Female	<760 µmol/d	<100 mg/d
Male	<380 µmol/d	<50 mg/d
Creatinine	8.8–14 mmol/d	1.0–1.6 g/d
Dopamine	392–2876 nmol/d	60–440 µg/d
Eosinophils	<100 eosinophils/mL	<100 eosinophils/mL
Epinephrine	0–109 nmol/d	0–20 µg/d
Glomerular filtration rate	>60 mL/min/1.73 m^2	>60 mL/min/1.73 m^2
	For African Americans, multiply the result by 1.21	For African Americans, multiply the result by 1.21
Glucose (glucose oxidase method)	0.3–1.7 mmol/d	50–300 mg/d
5-Hydroindoleacetic acid (5-HIAA)	0–78.8 µmol/d	0–15 mg/d
Hydroxyproline	53–328 µmol/d	53–328 µmol/d
Iodine, spot urine		
WHO classification of iodine deficiency:		
Not iodine deficient	>100 µg/L	>100 µg/L
Mild iodine deficiency	50–100 µg/L	50–100 µg/L
Moderate iodine deficiency	20–49 µg/L	20–49 µg/L
Severe iodine deficiency	<20 µg/L	<20 µg/L
Ketone (acetone)	Negative	Negative
17 Ketosteroids	3–12 mg/d	3–12 mg/d
Metanephrines		
Metanephrine	30–350 µg/d	30–350 µg/d
Normetanephrine	50–650 µg/d	50–650 µg/d
Microalbumin		
Normal	0.0–0.03 g/d	0–30 mg/d
Microalbuminuria	0.03–0.30 g/d	30–300 mg/d
Clinical albuminuria	>0.3 g/d	>300 mg/d
Microalbumin/creatinine ratio		
Normal	0–3.4 g/mol creatinine	0–30 µg/mg creatinine
Microalbuminuria	3.4–34 g/mol creatinine	30–300 µg/mg creatinine
Clinical albuminuria	>34 g/mol creatinine	>300 µg/mg creatinine
β_2-Microglobulin	0–160 µg/L	0–160 µg/L

Epithelial cell casts	None	
Granular casts	None	
Hyaline casts	0–5/low-power field	
Red blood cell casts	None	
Waxy casts	None	
White cell casts	None	
Sodium (varies with intake)	100–260 mmol/d	100–260 meq/d
Specific gravity:		
After 12-h fluid restriction	>1.025	>1.025
After 12-h deliberate water intake	≤1.003	≤1.003
Tubular reabsorption, phosphorus	0.79–0.94 of filtered load	79–94% of filtered load
Urea nitrogen	214–607 mmol/d	6–17 g/d
Uric acid (normal diet)	1.49–4.76 mmol/d	250–800 mg/d
Vanillylmandelic acid (VMA)	<30 µmol/d	<6 mg/d

Abbreviation: BCE = bone collagen equivalent.

Acknowledgment

The contributions of Drs. Daniel J. Fink, Patrick M. Sluss, James L. Januzzi, Kent B. Lewandrowski, Amudha Palanisamy, and Scott Fink to this chapter in previous editions are gratefully acknowledged. We also express our gratitude to Drs. Alex Rai and Jeffrey Jhang for helpful suggestions.

480e The Clinical Laboratory in Modern Health Care

Anthony A. Killeen

Modern medicine relies extensively on the clinical laboratory as a key component of health care. It is estimated that, in current practice, at least 60–70% of all clinical decisions rely to some extent on a laboratory result. For many diseases, the clinical laboratory provides essential diagnostic information. As an example, histopathologic analysis provides basic information about histologic type and classification of tumors and their degree of invasion into adjacent tissues. Microbiologic testing is required to identify infectious organisms and determine antibiotic susceptibility. For many common diseases, expert groups have produced standard guidelines for diagnosis that rely on defined clinical laboratory values, e.g., blood glucose or hemoglobin A_{1C} levels form the basis for diagnosis of diabetes mellitus; the presence of specific serum antibodies is required for diagnosis of many rheumatologic diseases; and serum levels of cardiac markers are a mainstay in diagnosis of acute coronary syndromes.

With their ever-increasing number and scope, clinical laboratory tests provide the clinician with a powerful set of tools but pose challenges in terms of appropriate selection and judicious, cost-effective use to deliver effective patient care.

RATIONALE FOR PERFORMING CLINICAL LABORATORY TESTS

DIAGNOSIS OF DISEASE

One of the most frequent reasons for performing clinical laboratory tests is to support, confirm, or refute a diagnosis of disease that is suspected on the basis of other information sources, such as history, physical examination findings, and imaging studies. The following questions need to be considered: Which clinical laboratory tests may be of value in supporting, confirming, or excluding the clinical impression? What is the most efficient test-ordering strategy? Will a positive test result confirm the clinical impression or even definitively establish the diagnosis? Will a negative result disprove the clinical suspicion, and, if so, what further testing or alternative approach will be needed? What are the known sources of false-positive and false-negative results, and how are these misleading results recognized?

SCREENING FOR DISEASE

Another reason for ordering clinical laboratory tests is to screen for disease in asymptomatic individuals (Chap. 4). Perhaps the most common examples of this application are the newborn screening programs now routinely used in most developed countries. Their purpose is to identify newborns with treatable conditions for which early intervention—even before clinical symptoms develop—is known to be beneficial. In adults, screening tests for diabetes mellitus, renal disease, prostate cancer (measurement of serum prostate-specific antigen [PSA] levels), and colorectal cancer (testing for occult blood in stool), for example, are widely applied to apparently healthy individuals on the grounds that early diagnosis and intervention lead to improved long-term outcomes.

Differences between Screening Tests and Confirmatory Tests It is important to distinguish between clinical laboratory tests that can be used to *screen* for disease and those that offer a *confirmatory result*. Screening tests are generally less expensive and more widely available than are confirmatory tests, which often require more specialized equipment or personnel. As a general principle, screening tests are designed to identify all individuals who have the disease of interest, even if, in the process, some healthy individuals are misidentified as possibly having the disease. In other words, maximization of the diagnostic sensitivity of screening tests inevitably comes at the expense of reduced diagnostic specificity. Confirmatory testing is intended to correctly separate those individuals who have a disease from those who do not.

These principles are exemplified by screening for hepatitis C virus (HCV) infection. A common approach is to test first for the presence of antibodies to HCV in serum. A positive result generally indicates either a current infection or a previous infection that the patient's immune system has successfully cleared. In the latter situation, antibodies may persist at detectable levels for life. However, a small proportion of patients have false-positive results in the serologic screening test for HCV. To resolve uncertainty in these instances, a positive serologic screening test should be followed by confirmatory identification of HCV RNA with molecular techniques. This confirmatory testing can provide evidence of current viral infection and can identify patients who are not infected.

RISK ASSESSMENT OF FUTURE DISEASE

Another reason for clinical laboratory testing is to assess a patient's risk of developing disease in the future. A number of diseases are associated with well-established clinical laboratory–defined risk factors that, if present, indicate the need for more frequent monitoring for the disease in question. The need for risk assessment is even clearer if there are useful interventions that decrease the risk of developing disease. For example, hypercholesterolemia is a well-established risk factor for coronary artery disease that may be modified by pharmacologic intervention (Chap. 291e). Many genetic mutations are known to be associated with increased risk of cancer. For example, hereditary mutations in the *BRCA1* and *BRCA2* genes predispose to breast and/or ovarian cancer. Individuals who are known to carry these mutations require more vigilant monitoring for early signs of cancer and may even opt for prophylactic surgery in an attempt to prevent cancer (Chap. 84). Individuals with factor V Leiden are at increased risk of developing deep venous thrombosis and may benefit from prophylactic anticoagulation in the perioperative period.

MONITORING DISEASE AND THERAPY

Many clinical laboratory tests offer useful information on the progress of disease and the response to therapy. One example is the measurement of viral load in HIV-1-infected patients who are taking antiretroviral agents. According to current guidelines from the Centers for Disease Control and Prevention, a successful antiretroviral response is defined by a fall in plasma HIV-1 levels of 0.5 $\log_{10}$ copies/mL, and a key goal of treatment is a reduction in the viral load to below the level of detection, which is typically in the range of 40–75 copies/mL. Other examples of the use of clinical laboratory testing for monitoring disease include measurement of tumor markers such as PSA, especially following surgical removal of tumors. In this situation, the expectation is that successful treatment of a tumor will cause a decrease in the level of the tumor marker. A later increase in the level of the tumor marker suggests a recurrence of the disease. Finally, the clinical laboratory offers direct monitoring of levels of some therapeutic agents, such as drugs. This monitoring is important if a drug has a defined therapeutic concentration range above which it is toxic and below which it is ineffective. Monitoring of drug levels in this situation facilitates optimal dosing and avoidance of toxicity.

CRITICAL VALUES

It is common practice for clinical laboratories to establish a list of "critical values." These are values of test results that indicate immediate risk to the health or life of the patient and therefore require urgent communication with the patient's physician so that appropriate medical intervention may be initiated. Critical values are reported regardless of whether the test was ordered as a "stat" or a routine test. The critical values themselves are generally created by the clinical laboratory medical director in conjunction with the medical staff. A representative list of critical values is shown in Table 480e-1.

"STAT" ORDERS

Tests that are ordered on a "stat" basis receive priority in the clinical laboratory's testing queue; testing of specimens from other patients may be delayed while a stat specimen is analyzed. Ordering a test stat

TABLE 480e-1 SELECTED EXAMPLES OF LABORATORY CRITICAL VALUES

Value	Less Than	Greater Than
Chemistry		
Ammonia		>100 µmol/L
Calcium, ionized	<3 mg/dL	>7 mg/dL
Calcium, total	<6 mg/dL	>14 mg/dL
Carboxyhemoglobin		>10%
Creatine kinase, total		>1000 U/L
CO_2, total	<11 mol/L	>45 mmol/L
Digoxin		>2.5 µg/L
Glucose	<40 mg/dL	>500 mg/dL
Glucose—CSF	< 40 mg/dL	
Ketone		>1.5 mmol/L
Lithium		> 2.0 mmol/L
Magnesium		>7 mg/dL
Methemoglobin		>35%
Osmolality	<250 mmol/L	>340 mmol/ L
Phosphorus	<1 mg/dL	
pH	<7.1	>7.6
Pco_2	<20 mmHg	>75 mmHg
Po_2, arterial	<40 mmHg	
Po_2, capillary	<30 mmHg	
Bicarbonate	<11 mol/L	>45 mol/L
Potassium	<2.7 mmol/L	>6 mmol/L
Salicylate		>30 mg/L
Sodium	<120 mmol/L	>160 mmol/L
Troponin		>0.120 µg/L
Hematology		
INR		>6.0
PTT		>105 secs
Hemoglobin	<7 g/dL	
WBCs	<1 $\times 10^9$/L	>50 $\times 10^9$/L
Platelets	<50 $\times 10^9$/L	>1000 $\times 10^9$/L
Microbiology[a]		
Acid fast culture or smear		
Blood culture		
CSF Gram stain/culture		
CSF cryptococcal antigen		
Malarial smear		

[a]Any positive result is critical.

Abbreviations: CO_2, carbon dioxide; CSF, cerebrospinal fluid; INR, international normalized ratio; Pco_2, partial pressure of carbon dioxide; Po_2, partial pressure of oxygen; PTT, partial thromboplastin time; WBCs, white blood cells.

should be reserved for situations in which a result is needed for urgent medical care—a judgment that must be made by the ordering physician. Stat testing should not be used merely for the convenience of either the patient or the health care provider.

SENSITIVITY AND SPECIFICITY IN THE CLINICAL LABORATORY

The commonly used metrics of a clinical laboratory test are the diagnostic sensitivity, specificity, and positive and negative predictive values. These concepts are discussed in Chap. 3. In the clinical laboratory, the terms *sensitivity* and *specificity* have alternative meanings that are applied to tests, and the different uses of these terms may cause confusion. *Analytic sensitivity* can refer to the lowest detectable concentration of analyte that can be measured with some defined certainty or to the rate of change of signal intensity as analyte concentration changes. For example, newer generations of laboratory assays frequently exhibit improved sensitivity over that of earlier generations, i.e., they can detect lower concentrations of the analyte—a feature that is often of value in disease diagnosis. *Analytic specificity* refers to the extent to which other substances in the test system interfere with measurement of the analyte of interest. This concept is frequently applied to immunoassays, in which a detection antibody may also bind with compounds that have a structure similar to the substance sought. For instance, immunoassays for drugs may show cross-reactivity with drug metabolites, and immunoassays for glucocorticoids may show cross-reactivity with other glucocorticoids of similar structure. Certain chemical assays are also subject to nonspecificity. For example, the Jaffe reaction, a chemical method commonly used to measure creatinine, is subject to positive interference from a number of other compounds, including glucose, certain ketones, and cephalosporin antibiotics. Elevated concentrations of bilirubin, free hemoglobin, or turbidity in plasma or serum specimens may also interfere with some assays. The clinical laboratory should be able to provide advice about the presence or magnitude of these effects in the assays it performs.

CLINICAL LABORATORY DIAGNOSTIC PRINCIPLES

Clinical laboratory diagnosis, like all diagnosis, is based on observation of disease-related changes from normality.

1. Tissue injury or necrosis allows leakage of intracellular components into the circulation, with consequent detectable rises in blood levels of these components. Many intracellular molecules are common across tissue types and are therefore not indicative of injury to a specific tissue. Other constituents are selectively expressed in relatively high concentrations—or are even uniquely present—in certain tissues. Therefore, their presence in the blood is evidence of injury to that tissue. This principle forms the rationale for measurement of blood levels of, for example, liver enzymes in evaluating liver disease (Chap. 358), cardiac troponins in acute coronary syndromes (Chap. 295), and myoglobulin in muscle injury. The extent of the rise in blood levels of these markers generally correlates with the extent of tissue damage, although there are exceptions; for example, liver enzyme levels may fall in end-stage liver disease.
2. An increase in blood levels of some analytes indicates failure of normal excretory processes. This principle is illustrated by elevations in conjugated bilirubin that accompany obstruction of the biliary system, by elevations in ammonia in advanced or metabolic liver disease, by rises in creatinine and potassium levels in renal failure, and by increases in Pco_2 in some pulmonary diseases.
3. Increases in the blood concentration of tissue-specific markers may result from expansion of the total volume of that tissue. This principle forms the basis for the measurement of levels of many tumor markers such as PSA (prostate cancer), CA-125 (ovarian cancer), CEA (colon cancer), and CA-19–9 (pancreatic cancer). In practice, the usefulness of these markers varies with the degree to which they are produced by a tumor and by the tumor's size. Small colon cancers, for example, may not produce a significant rise in CEA levels, whereas small prostate cancers often produce detectable rises in PSA concentrations.
4. Disease processes often manifest characteristic patterns of coincident changes in levels of several analytes. These patterns of change can be understood by consideration of the underlying pathophysiology. For example, acute intravascular hemolysis is characterized by a fall in levels of hemoglobin and haptoglobin and by a rise in unconjugated bilirubin. In endocrine diseases, there are often changes in concentrations of several hormones because of disturbance of feedback loops. Primary hyperthyroidism, as an example, is characterized by increases in thyroxine and by suppression of thyroid-stimulating hormone. In diabetic ketoacidosis caused by insulin deficiency, there are concomitant elevations of plasma glucose, ketones, and (frequently) potassium. In response to metabolic acidosis, levels of bicarbonate are typically reduced.
5. Genetic changes underlie many diseases, both inherited and acquired. In the era of molecular medicine, there is increasing recognition of the contribution of hereditary factors to many common diseases. Often, the epidemiology of common diseases such as hypertension is characterized by a minority of families that have

mutations in recognized genes, whereas the genetic basis of the same disease phenotype in the larger population is unclear. The search for the genetic factors that contribute to many common diseases remains a topic of intense research interest. It is now clear that essentially all tumors have genetic abnormalities. Although there is an inherited predisposition in some families, most of these genetic changes are acquired. Identification of the genetic abnormalities in cancer offers new tools for clinical laboratory diagnosis and classification of tumors in ways that surpass traditional histopathology and also provides insights into cellular processes that may be targets for treatment.

6. Clinical laboratory results should always be interpreted in the context of the patient's history and physical examination as well as any other relevant information (e.g., imaging studies). The clinician should avoid treating laboratory results rather than the patient.
7. Recommended clinical laboratory tests change with time. As new markers of disease emerge, they may replace older markers. For example, measurement of serum creatine kinase (CK) levels was introduced for diagnosis of acute myocardial infarction in the 1980s. Use of the cardiac-specific isoenzyme CK-MB later became widespread in clinical practice. Today, cardiac troponins are replacing CK (or CK-MB) measurements in recommended guidelines. Many other assays have fallen out of use as better assays have become available. Measurement of urine 17-ketosteroids (arising from androgens) and of urine 17-hydroxycorticosteroids (arising from glucocorticoids) has been supplanted by immunoassays or mass spectroscopy determinations of specific steroid hormones. Today, many steroid hormones are measured by mass spectrometry, often with better analytic specificity than is provided by immunoassays. As new tests are introduced, it is essential that they be evaluated critically before adoption for clinical use. At a minimum, consideration needs to be given to questions of clinical validation, specimen stability, diagnostic sensitivity and specificity, positive and negative predictive values, analytic accuracy and precision, and relative costs.

REFERENCE RANGES

In the interpretation of clinical laboratory results, comparison is usually made to a reference range (sometimes called a normal range) that defines the values seen in health or considered to be desirable for health. Several common methods are used to describe reference ranges in the clinical laboratory.

1. For many quantitative clinical laboratory tests, the range of observed values in a healthy population shows an approximately Gaussian distribution. The factors that contribute to this range include the inter- and intraindividual variation in the concentration of the analyte and the analytic imprecision. When there is an approximately Gaussian distribution of values in the population, the reference range is commonly defined as being the central 95% of the range of distribution of those values. According to this method, 2.5% of the population will have a measured value that is below the reference range for the analyte, and 2.5% will have a value that is above the reference range. The fact that 5% of healthy individuals will have a test value that is outside the reference range has important implications when multiple tests are ordered. If N independent tests are performed on a specimen, then the probability that at least one result will be outside the reference range is $(1–0.95^N)$. The greater the number of tests ordered (even for a healthy individual), the greater is the likelihood of an abnormal result (Fig. 480e-1). If 20 independent tests are performed on a healthy subject, the probability of at least one abnormal result is almost two-thirds.

In some settings, a narrower range of values is considered to be abnormal. For example, current American Heart Association guidelines recommend the use of a serum level of cardiac troponins that is greater than the 99th percentile of values found in a healthy population as evidence of acute myocardial infarction.

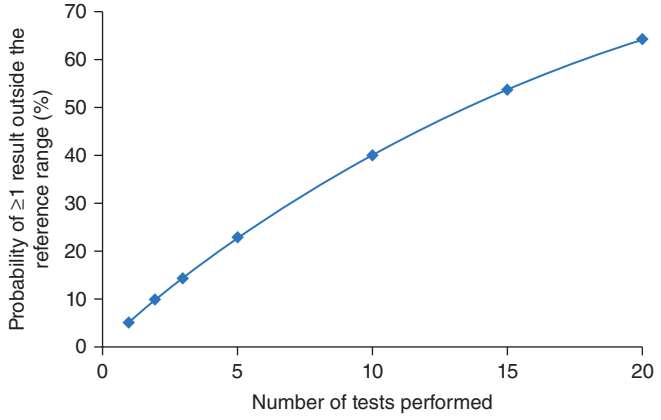

FIGURE 480e-1 Probability that at least one laboratory result will be abnormal in a healthy individual as an increasing number of independent tests are performed. The reference range is the central 95% of values measured in a healthy population.

2. An alternative approach to using population means and standard deviations is to define a range of analyte values that is judged to be consistent with health on the basis of expert consensus opinion. These ranges are often referred to as *decision limits*. Examples of reference ranges established in this way include those for total, high-density, and low-density cholesterol (Table 480e-2). Such ranges may deviate considerably from those that would be established if the analyte concentrations of the population (mean ± 2 standard deviations) were used as a basis for establishing the reference range. For example, the "desirable" total cholesterol value according to the National Cholesterol Education Program is <200 mg/dL. This value is actually very close to the mean concentration among U.S. adults; in fact, almost one-half of U.S. adults have a total cholesterol concentration that is above the "desirable" range. If the central 95% of cholesterol concentrations in the population were taken as the reference range, the upper end of that range would be ~240 mg/dL, well beyond what is considered desirable.

Reference ranges may vary with age, gender, ethnic background, and physiologic state (e.g., pregnancy, high-altitude adaptation). Some examples of these variations are shown in the Appendix. The existence of different reference ranges poses challenges for interpretation of results. In particular, creatinine stands out as an analyte for which conventional reference ranges are not always easy to apply in clinical practice. Plasma levels of creatinine vary with age, gender, and ethnic group. This fact makes it difficult in practice to use a simple reference

TABLE 480e-2 NATIONAL CHOLESTEROL EDUCATION PROGRAM ADULT TREATMENT PANEL III GUIDELINES FOR CHOLESTEROL

Cholesterol Type	Level (mg/dL)
LDL	
Optimal	<100
Near optimal/above optimal	100–129
Borderline high	130–159
High	160–189
Very high	≥190
Total	
Desirable	<200
Borderline high	200–239
High	≥240
HDL	
Low	<40
High	≥60

Abbreviations: HDL, high-density lipoprotein; LDL, low-density lipoprotein.

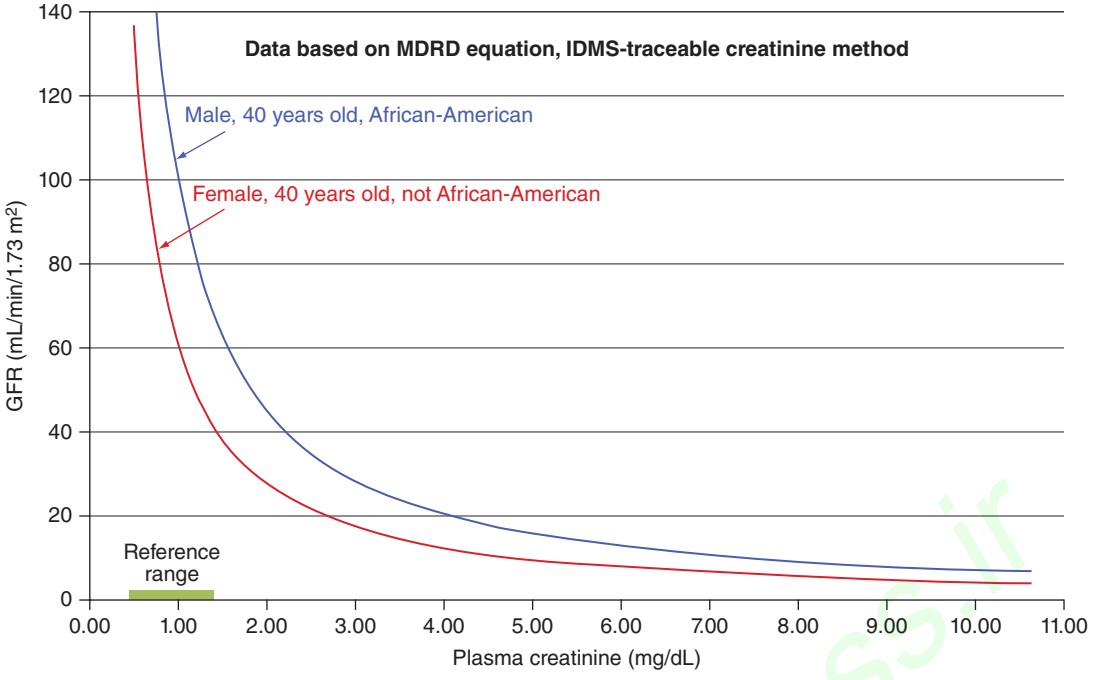

FIGURE 480e-2 Relationship between plasma creatinine and estimated glomerular filtration rate (eGFR) using the 4-parameter Modification of Diet in Renal Disease (MDRD) equation. IDMS, isotope dilution mass spectrometry.

range for this analyte when attempting to gauge a patient's renal function. A large decrease in glomerular filtration rate (GFR) is associated with slight increases in the plasma creatinine concentration within the typical reference range provided by many laboratories (Fig. 480e-2). A 60-year-old white woman with a serum creatinine level of 1.00 mg/dL, which is well within the typical reference range, has an estimated GFR of only 57 mL/min per 1.73 m^2, whereas the same creatinine concentration in a 20-year-old African-American male is consistent with normal renal function. To better estimate the GFR, which is widely considered to be the most useful index of overall renal function, it has become customary to use equations that incorporate plasma creatinine with other parameters. The most widely used of these equations in current practice is the 4-parameter Modification of Diet in Renal Disease (MDRD) equation that incorporates plasma creatinine, age, gender, and ethnic group (African American or not African American). The more recent CKD-EPI equation, which uses the same 4 parameters, is beginning to replace the MDRD equation. Recommended clinical laboratory practice is to report the estimated GFR with all creatinine measurements in adults. This addition provides more useful information than would a creatinine reference range alone.

SOURCES OF ERROR IN CLINICAL LABORATORY TESTING

Errors can arise at all stages of the testing process, from specimen collection to result interpretation. An error arising at any stage may adversely affect patient care. In clinical laboratory practice, it is customary to divide the testing process into three phases: preanalytic, analytic, and postanalytic. Examples of each type of error are shown in Table 480e-3. The most common error in the testing process is specimen mislabeling, in which a specimen from one patient is placed in a container labeled with another patient's name or identifiers. Specimen mislabeling errors may have very serious consequences for a patient. For example, if erroneous typing of a patient's blood group results from specimen mislabeling and is followed by transfusion of a mismatched unit of blood, the outcome may be fatal. A mislabeled biopsy specimen can lead either to an erroneous diagnosis and inappropriate therapy or to a failure to make a diagnosis and institute appropriate therapy.

In addition to errors, many preanalytic factors can influence clinical laboratory results. Posture (i.e., recumbent versus upright), exercise, diet, recently ingested food, and use of prescribed or recreational drugs (including tobacco, alcohol, caffeine, and herbal supplements) can influence a variety of analyte concentrations. After blood has been collected, certain analytes undergo changes in their concentration during storage or transportation. Glucose levels fall as a result of red cell metabolism. Ammonia levels rise as a result of protein breakdown. Increasing permeability and breakdown of red cell membranes leads to increases in plasma potassium and free hemoglobin levels. Bacterial contamination can lead to overgrowth of specimens. To minimize

TABLE 480e-3 EXAMPLES OF PREANALYTIC, ANALYTIC, AND POSTANALYTIC ERRORS DURING THE LABORATORY TESTING PROCESS

Preanalytic Sources of Error
Test selection
Inappropriate test for the clinical need
Lack of clinical usefulness, regardless of possible results
Test order misunderstood or not communicated
Specimen collection
Incorrect time of collection
Patient not prepared for collection (e.g., not fasting)
Incorrect specimen type (e.g., wrong anticoagulant, wrong tissue fixative)
Use of incorrect specimen container
Insufficient specimen collected
Contamination of specimen by IV fluids, drugs, or bacteria
Specimen mislabeled or unlabeled
Important clinical information not provided
Delays in transportation to the lab, leading to alterations in specimen constituents
Analytic Sources of Error
Incorrect storage conditions prior to analysis
Specimen misidentification in the laboratory
Wrong test performed
Assay interferences
Assay failure (e.g., assay out of control)
Postanalytic Sources of Error
Delay in communication of assay results
Results not communicated to correct person
Incorrect result communicated
Misinterpretation of result

these precollection alterations, specimens should be processed or transported to the clinical laboratory as soon as possible after collection. The list of known preanalytic variables and their effects is extensive, and the reader is referred to the compendium on this subject (see Young DS: *Effects of Preanalytical Variables on Clinical Laboratory Tests,* 3rd ed. Washington, DC, AACC Press, 2007).

POINT-OF-CARE TESTING

The great majority of tests continue to be performed in dedicated clinical laboratory facilities, but for several decades there has been a trend toward point-of-care testing. This change has been made possible by the development of portable analytic devices, including single-purpose instruments such as glucometers and oxygen saturation monitors, and multifunction instruments that can perform a wider variety of analyses, particularly in chemistry and hematology but also in some areas of microbiology. The use of these devices is driven largely by the convenience of faster result availability. In some settings (e.g., in rural areas and developing countries), there may be no easily accessible clinical laboratory and a point-of-care device may be the best or only option for testing. However, the per-specimen cost of point-of-care testing, in terms both of reagents and supplies and of personnel, is often greater than that of centralized testing. Other concerns relate to the adequacy of personnel training for point-of-care testing, the quality of the results, and the incorporation of results into the medical record.

HOME TESTING BY PATIENTS

One of the largest markets for point-of-care testing is home testing by patients, which has long been an important element in the management of persons with diabetes who monitor their own blood glucose levels. Over-the-counter kits for home pregnancy testing have been available for decades. More recently, kits have become available for home testing of the international normalized ratio or prothrombin time by patients taking oral anticoagulants. Kits are also available for cholesterol monitoring, fecal occult-blood detection, and hemoglobin measurement. In these areas, there is often little information on the quality of test performance, the accuracy of the results, or the correctness of result interpretation.

ISSUES SPECIFIC TO GENETIC TESTING

The principles of genetic medicine in clinical practice are discussed in Chaps. 82–84. Here we will concentrate on issues related to clinical laboratory testing for genetic disease.

The distinction between genetic testing for inherited disorders and that for acquired disorders affects the type of tissue that should be obtained for analysis. In inherited disorders, all nucleated cells are expected to carry the inherited mutation; thus white blood cells or buccal cells (obtained by scraping the inside of the cheek) are convenient sources of DNA for clinical laboratory testing. For prenatal testing of the fetus, chorionic villi or amniocytes are commonly used. In tests for acquired genetic disorders (e.g., in tumors), the tissue of interest that contains a suspected mutation must be sampled. It is often useful to compare tumor DNA with the patient's normal DNA in order to identify acquired mutations (e.g., testing for microsatellite instability in colorectal cancer; Chap. 101e).

INFORMED CONSENT FOR GENETIC TESTING

Although it is assumed that all clinical laboratory testing is performed with the consent of the patient (or, in the case of minors, the parents), regulations may require formal written consent for genetic testing. Such regulations vary among jurisdictions, and the practicing clinician should be aware of local regulations. In some jurisdictions, there are regulations on the storage and use of genetic information and on the maximal period for which genetic specimens may be stored.

For some late-onset genetic diseases, such as Huntington's disease (Chap. 449), genetic testing allows a prediction about the future development of the disease. The degree of certainty that is possible on the basis of this testing surpasses that associated with identification of more traditional disease risk factors (e.g., hyperlipidemia as a risk factor for future myocardial infarction). When deciding to undertake predictive genetic testing, it is important for the patient to consider the broad implications of a positive or negative test result, to be made aware of any support and counseling that is available, and to understand the implications of a result for other family members. In dealing with these issues, genetic counselors play an important role (Chap. 84). Their expertise includes the ability to explain genetic disorders at an understandable level to patients and their families, to arrange for support services, and to provide genetic risk assessments to members of families with genetic disorders.

When testing for genetic disorders, the clinical laboratory will use different analytic approaches according to the disease of interest. Some disorders, such as sickle cell anemia, are caused by single-point mutations. Testing for these disorders involves mere assessment for one or a few mutations in a single gene. Other disorders (e.g., hyperphenylalaninemias) may be caused by numerous mutations in a single gene. Still others (e.g., hereditary breast cancer) may be caused by mutations in many genes. The number of possible mutations and genes that underlie a clinical phenotype affects the cost of and time required for clinical laboratory testing as well as the likelihood of finding a disease-causing mutation.

If a disease phenotype can be caused by many mutations, a clinical laboratory result that is negative should be interpreted with care. For example, it is common to screen healthy pregnant women (and their partners) for mutations in the *CFTR* gene, which is mutated in patients with cystic fibrosis (CF). The goal of this screening is to identify women who are carriers of a *CFTR* mutation and therefore are at increased risk of having a baby with CF. Because CF is an autosomal recessive disorder, a fetus has a 1:4 chance of being affected if both parents are carriers of disease-causing *CFTR* mutations. The screening test approach that is commonly used to identify mutations in carriers detects 80–85% of all known disease-causing *CFTR* mutations in Caucasians and up to 97% of mutations among Ashkenazi Jews. A negative screening result therefore does not completely eliminate the possibility that a woman (or her partner) actually has a mutation. What can be inferred from a negative test result is that the risk of having a CF-affected baby has decreased significantly to an extent that depends on the woman's ethnic group and the mutations that were examined. The clinical laboratory should calculate and report the woman's new risk of being a carrier if the screening result is negative.

The increasing availability of large-scale (next-generation) sequencing of a patient's whole genome or exome will greatly affect genetic testing over the next decade, with implications for the number of mutations that can be detected and the increased complexity of result interpretation.

LIMITATIONS TO MOLECULAR GENETIC TESTING

Genetic testing has limitations that are often unique to this field. Results may be inconclusive. For example, a search for mutations in a gene that is suspected of causing a disease may fail to reveal any known disease-causing mutations. A mutation may be discovered that is of unknown clinical significance. In this situation, consideration of the predicted change in the amino acid sequence of the encoded protein may suggest a biologic effect—e.g., replacement of a charged amino acid by one of the opposite charge or by a neutral amino acid; replacement of an amino acid by one of a different size; or replacement of an amino acid that is conserved across multiple species. Further information may be obtained by determining whether the mutation is found in healthy individuals. Even with all of these considerations, it is not uncommon that the biologic significance of an identified mutation remains uncertain, and further research may be needed to assess its significance.

It is also important to understand the limitations of the clinical laboratory approach used to detect mutations. At this time, next-generation sequencing remains an impractical undertaking for financial reasons, although extensive sequence analysis has become the

standard of care for a few genes (e.g., analysis of *BRCA1* and *BRCA2* in assessing the risk of breast and ovarian cancer in individuals with a strong family history of these disorders). As sequencing technologies become less expensive, they can be expected to be more commonly used for both identifying mutations in patients with genetic disorders and screening asymptomatic individuals at risk of genetic disease.

Another unique aspect of genetic testing is the concern that genetic information about individuals may be used to discriminate against them by employers or by insurance companies. In the United States, the Genetic Information Nondiscrimination Act of 2008 (GINA) prohibits the use of genetic information by employers in making decisions related to employment and by health insurance companies in issuing insurance policies or setting premium rates based on knowledge of the applicant's genetic status. GINA does not cover disability insurance, long-term care insurance, or life insurance policies.

Although public attention has been most closely focused on DNA testing, other clinical laboratory investigations that are not usually thought of as genetic may provide important genetic information about the person being tested. For example, serum protein electrophoresis may reveal α-1 antitrypsin deficiency. Depending on the clinical laboratory technology used, measurement of hemoglobin A_{1C}, commonly used for monitoring diabetes control, may reveal a hemoglobin variant such as HbS (sickle cell). Measurement of cholesterol and triglyceride levels may reveal any of a number of hereditary disorders. All of these results are types of genetic information.

REGULATION OF THE CLINICAL LABORATORY

In the United States, all clinical laboratory testing performed for clinical purposes (but not for research purposes) is regulated by the federal Clinical Laboratory Improvement Amendments Act of 1988 (CLIA). Home monitoring by patients who are testing their own specimens is not covered by CLIA. The statute and the regulations, which are administered by the Centers for Medicare and Medicaid Services, apply to all laboratories, whether located in a physician's office, a large hospital, or a reference laboratory; and all laboratories are required to hold a valid CLIA certificate that is appropriate for the highest complexity level of the tests they perform. The U.S. Food and Drug Administration is responsible for assigning the complexity level of commercial tests. The lowest category of complexity is the "waived" category, which is followed (in order of increasing complexity) by the categories of "provider-performed microscopy," "moderate-complexity testing," and "high-complexity testing." The category of provider-performed microscopy is used to cover tests such as the use of potassium hydroxide preparations on skin scrapings to examine for fungi, fern tests, and sperm motility tests; it does not encompass histopathology that falls into the high-complexity category. Even if a clinical laboratory is performing only testing in the "waived" category, it must still hold a valid CLIA certificate. Laboratories that hold certificates for nonwaived tests are required to participate in proficiency testing and are regularly inspected to monitor their performance.

481e Clinical Procedure Tutorial: Central Venous Catheter Placement

Maria A. Yialamas, William E. Corcoran, Gyorgy Frendl, Kurt Fink

Clinical procedures are an important component of medical student and resident training, and some are required for board and hospital certification. In these *Harrison's* **Chaps. 481e–486e**, video tutorials are presented for performing abdominal paracentesis, thoracentesis, endotracheal intubation, central venous catheter placement, percutaneous arterial blood gas sampling, and lumbar puncture. These videos have been created specifically for *Harrison's*. Each includes the indications, contraindications, equipment, potential complications, and related patient safety considerations. Additional video tutorials covering clinical procedures such as breast biopsy, IV line insertion, phlebotomy, arterial line insertion, arthrocentesis, bone marrow biopsy, pelvic examination, thyroid aspiration, basic suturing, and urethral catheterization are available to subscribers of *Harrison's Online* and AccessMedicine (available at *www.accessmedicine.com*).

483e Clinical Procedure Tutorial: Abdominal Paracentesis

Maria A. Yialamas, Anna E. Rutherford, Lindsay King

Clinical procedures are an important component of medical student and resident training, and some are required for board and hospital certification. In these new *Harrison's* **Chaps. 481e–486e** video tutorials are presented for performing abdominal paracentesis, thoracentesis, endotracheal intubation, central venous catheter placement, percutaneous arterial blood gas sampling, and lumbar puncture. These videos have been created specifically for *Harrison's*. Each includes the indications, contraindications, equipment, potential complications, and related patient safety considerations. Additional video tutorials covering clinical procedures such as breast biopsy, IV line insertion, phlebotomy, arterial line insertion, arthrocentesis, bone marrow biopsy, pelvic examination, thyroid aspiration, basic suturing, and urethral catheterization are available to subscribers of *Harrison's Online* and AccessMedicine (available at *www.accessmedicine.com*).

INDEX

Page numbers in **bold** indicate the start of the main discussion of the topic. Page numbers followed by "f" or "t" refer to the page location of figures and tables, respectively, and a "v" indicates a video on the DVD. Numbers containing "e-" followed by a number (e.g., 91e-3) refer to pages in the e-chapters on the DVD.

Hydroxocobalamin (vitamin B_{12A})
for cobalamin deficiency, 648
as cyanide antidote, 262e-7–8, 262e-8t, 473e-11t
β-Hydroxybutyrate, 318, 2434
4-Hydroxybutyric aciduria, 434e-2t
Hydroxychloroquine
adverse effects of, 2130t
common, 2146t
cutaneous, 353, 380
myopathy, 462e-20, 462e-20t, 2218t
neuropathy, 2686, 2687t
ocular, 206
serious, 2146t
for calcium pyrophosphate deposition disease, 2236
for hypercalcemia, 314
for infective endocarditis, 823t
for malaria prophylaxis, 1383t
monitoring during treatment with, 2146t
overdosage/poisoning with, 473e-13t
for porphyria cutanea tarda, 390, 2530
for Q fever, 1162
for rheumatoid arthritis, 2145, 2146t
for sarcoidosis, 2211, 2212t
for SLE, 2130t, 2132
for Whipple's disease, 1094
2-Hydroxyglutarate (2-HG), 102e-13
Hydroxykynureninuria, 434e-2t
7α-Hydroxylase, 1934
11β-Hydroxylase, 434
11β-Hydroxylase deficiency
clinical features of, 306, 1620, 1620t, 2313, 2357
diagnostic markers of, 2328t
genetic considerations in, 1620t
pathophysiology of, 1621f
17α-Hydroxylase (CYP17), 372e-24t
17α-Hydroxylase deficiency
clinical features of, 306, 1620t, 1621, 2353, 2354t
diagnostic markers of, 2328t
genetic considerations in, 2353, 2354t
genetics of, 1620t
hypergonadotropic hypogonadism in, 337
hypertension in, 1621
pathophysiology of, 1621f
21-Hydroxylase (CYP21), 372e-24t
21-Hydroxylase antibodies, 2346
21-Hydroxylase deficiency
classic. *See* Congenital adrenal hyperplasia (CAH)
classic simple virilizing, 2355
diagnosis of, 333
nonclassic, 2355
salt-wasting, 2355–2356
21-Hydroxylase gene mutations. *See CYP21A2* (21-hydroxylase gene) mutations
Hydroxyl radicals, 103e-4
3-Hydroxy-3-methylglutaric aciduria, 434e-3t
17-Hydroxyprogesterone, 2329, 2760t
3β-Hydroxysteroid dehydrogenase deficiency, 2328t, 2357
11β-Hydroxysteroid dehydrogenase, 64e-8, 64e-8f, 611, 2312
11β-Hydroxysteroid dehydrogenase deficiency. *See* Syndrome of apparent mineralocorticoid excess (SAME)
17β-Hydroxysteroid dehydrogenase deficiency, 2353

Hydroxyurea
  action of, 103e-4, 103e-10t, 103e-14, 632
  adverse effects of, 103e-10t, 379, 649
  for chronic myelomonocytic leukemia, 135e-6
  for CML, 694
  for hypereosinophilic syndromes, 423
  for sickle cell anemia, 636
Hydroxyzine
  for angioedema, 2119
  for ciguatera poisoning, 2742
  for pruritus, 345
  for urticaria, 2119
Hygiene hypothesis, 1670
Hymen, imperforate, 335
Hymenolepiasis diminuta, 1434
Hymenolepiasis nana (dwarf tapeworm), 245e-2t, 246e-11, 765t, 1434
Hymenoptera venom/sting, 2116, 2748–2749
Hyoscyamine, 473e-8t, 2672
Hypalgesia, 158
Hyperabduction maneuver, 1647
Hyperacute rejection, 1827
Hyperaldosteronism
  diagnosis of, 307, 1618–1619
  familial type I. *See* Glucocorticoid-remediable aldosteronism (GRA)
  familial types II and III, 306
  genetic considerations in, 306, 307
  hyperreninemic, secondary, 321–322
  hypertension in, 1614, 1618
  hypokalemia in, 306
  idiopathic, 306
  metabolic acidosis in, 320–321
  mineralocorticoid excess in. *See* Mineralocorticoid excess
  primary, 306, 307, 1614, 1618–1619
  secondary, 306, 1614
  treatment of, 1619
  weakness in, 462e-119
Hyperalgesia, 87, 158
Hyperammonemia, 434e-3t, 434e-5, 435e-1t, 435e-2, 1996
Hyperamylasemia, 2089t
Hyperamylasuria, 2089t
Hyperbaric medicine, 477e-1, 477e-1f
Hyperbaric oxygen therapy, **477e-1**
  for acute coronary syndrome, 477e-4t
  adverse effects of, 477e-2
  for altitude illness, 476e-2t, 476e-3, 476e-4
  for carbon monoxide poisoning, 477e-5–6
  for chronic wounds, 477e-3, 477e-4t, 477e-5, 477e-5f
  contraindications to, 477e-2
  for decompression sickness, 477e-4t, 477e-8
  for gas gangrene, 833, 994
  for idiopathic sudden sensorineural hearing loss, 477e-4t
  indications for, 477e-3, 477e-3t
  for late radiation tissue injury, 477e-3, 477e-4t
  mechanisms of, 477e-1, 477e-2f
  for radiation therapy enhancement, 477e-4t
  for soft tissue infections, 1102
  for traumatic brain injury, 477e-4t
Hyperbilirubinemia, **2000**
  in alcoholic liver disease, 2053, 2053t
  approach to the patient, 281–282, 281f
  conjugated
    in benign recurrent intrahepatic cholestasis, 284, 2003t, 2004
    differential diagnosis of, 282
    in Dubin-Johnson syndrome, 282, 2003–2004, 2003t
    with other liver abnormalities
      approach to the patient, 281f, 282–283
      in cholestatic disorders, 283–285, 284t
      in hepatocellular disease, 283, 283t
    in progressive familial intrahepatic cholestasis, 284, 2003t, 2004
    in Rotor syndrome, 282, 2003t, 2004
    in sepsis/septic shock, 1756
  isolated, 281–282, 282t
  in pancreatitis, 2093
  pathophysiology of, 280
  unconjugated
    from decreased hepatic bilirubin clearance, 2001
    differential diagnosis of, 281–282, 282t
    from hereditary defects. *See* Crigler-Najjar syndrome; Gilbert's syndrome
    from increased bilirubin production, 2000
Hypercalcemia, **313**, **2469**
  in adult T-cell leukemia/lymphoma, 225e-4
  after kidney transplantation, 1831
  aluminum intoxication and, 2479
  asymptomatic, 2479
  bone turnover–associated, 2478
  chronic, 1862, 2479, 2479f
  in chronic kidney disease, 1815, 2478
  clinical features of, 96e-9t, 152, 313, 463e-4, 2469–2470
  diagnosis of, 314, 2469–2470, 2479fl
  differential diagnosis of, 2469–2470, 2479–2480, 2479fl
  ECG in, 269e-13f, 269e-14f, 1457, 1458f
  etiology of, 313, 313t, 2469, 2470t, 2480
  familial hypocalciuric. *See* Familial hypocalciuric hypercalcemia (FHH)
  genetic considerations in, 2475, 2476f
  in hyperparathyroidism. *See* Hyperparathyroidism, primary
  hypertension in, 1620
  hyperthyroidism and, 2478
  idiopathic, of infancy, 83e-6, 2477–2478
  immobilization and, 2478
  inpatient neurologic consultation for, 463e-4
  lithium therapy and, 2475
  malignancy-associated, **609**
    clinical features of, 610, 2479–2480
    clinical syndromes related to, 2475–2477
    diagnosis of, 610, 2476–2477
    etiology of, 609–610, 609t
    mechanisms of, 2476
    pathogenesis of, 609t
    treatment of, 610, 2477
  in metastatic bone disease, 119e-4
  in milk-alkali syndrome, 313, 2458, 2479
  in multiple myeloma, 714, 717
  in nephrogenic diabetes insipidus, 303
  in Paget's disease of bone, 426e-3
  with parenteral nutrition, 98e-7t
  pNET and, 559t, 571
  renal effects of, 1862
  in sarcoidosis, 2208, 2477
  thiazides and, 2478
  treatment of, 314, 610, 2480–2482, 2480t
  vitamin A intoxication and, 2478
  vitamin D–related, 2477–2478
Hypercalciuria
  in Bartter's syndrome, 306, 2483
  hematuria and, 294
  hypocalcemic, 2483
  loop diuretics and, 306
  nephrolithiasis risk and, 1867
  in Paget's disease of bone, 426e-3
Hypercapnia, 315
  metabolic alkalosis following, 322
  permissive, 322, 1741

HyperC-VAD regimen, 704
Hyperemesis gravidarum, 49, 259, 2300
Hypereosinophilic syndromes (HES)
  clinical features of, 135e-8, 1567, 1686, 2683
  diagnosis of, 135e-8, 135e-t
  diseases associated with, 422
  idiopathic, 422–423
  pathophysiology of, 372e-8, 1567
  subtypes of, 135e-7, 135e-7t, 1686
  treatment of, 135e-8, 1686
Hyperesthesia, 158
Hyperfiltration, glomerular, 333e-1
Hyperfiltration hypothesis, 333e-1
Hypergammaglobulinemia, 2050
Hypergastrinemia, 568, 1927
Hyperglobulinemia, 64e-6
Hyperglycemia
  β-agonists and, 312
  in cardiogenic shock, 1760
  clinical features of, 2406
  in diabetic ketoacidosis. *See* Diabetic ketoacidosis (DKA)
  hypernatremia in, 303
  hyponatremia in, 301
  in overdosage/poisoning, 473e-3
  in pancreatitis, 2092–2093
  with parenteral nutrition, 98e-7
  perioperative, 55
  in sepsis/septic shock, 1756
  with specialized nutritional support, 98e-4
  in systemic inflammatory response syndrome, 98e-4
Hyperglycemic hyperosmolar state (HHS), 2417t, 2420
Hypergonadotropic hypogonadism, 336–337
Hyperhidrosis, primary, 2643
Hyperhomocysteinemia
  cardiac manifestations of, 290e-1t, 290e-2
  clinical features of, 434e-4
  pyridoxine deficiency in, 96e-4
  risk factors for, 434e-4
  treatment of, 434e-4
  venous thrombosis risk in, 744
Hyperhomocystinurias, 434e-1, 434e-4
Hyperhydroxyprolinemia, 434e-2t
Hyper-IgD syndrome, 126
Hyper-IgE syndrome (Job's syndrome), **423**
  autosomal dominant, 375e-2, 2109
  autosomal recessive, 2109
  cellular/molecular defects in, 420t, 423
  clinical features of, 375e-2, 420t, 423, 830, 2109
  diagnosis of, 420t, 2109
  monocytosis in, 421
Hyper-IgM syndrome, 2110, 2110f, 2111
Hyperimmune equine immunoglobulin, 1328
Hyperimmunoglobulinemia D with periodic fever syndrome (HIDS), 2213t, 2215
Hyperinflation, 47e-1, 1702
Hyperinsulinemia, 98e-7, 332, 2405
Hyperinsulinism, endogenous, 2434
Hyperkalemia, **308**
  in acute kidney injury, 1808
  after adrenalectomy, 1619
  AV conduction block in, 1471t
  in chronic kidney disease, 333e-2, 1814, 1815
  clinical features of, 310–311
  definition of, 308
  diagnosis of, 311, 311f
  drug-induced, 43, 64e-2, 310
  ECG in, 310, 1457, 1458f
  etiology of, 304, 308–310, 309t
  in HIV infection, 310
  inpatient neurologic consultation for, 463e-4
  metabolic acidosis in, 64e-2–3
  in overdosage/poisoning, 473e-3
  with parenteral nutrition, 98e-7t
  rebound, 307
  renal effects of, 1862
  transfusion-related, 138e-5
  treatment of, 64e-3, 312, 463e-4
  in tumor lysis syndrome, 1795
  urinary tract obstruction and, 1872
  ventricular tachycardia in, 1489
Hyperkalemic periodic paralysis (HyperKPP)
  channelopathies in, 444e-2t
  clinical features of, 310, 462e-3, 462e-17–18, 462e-17t
  diagnosis of, 462e-18
  early interventions for, 450t
  genetic considerations in, 444e-2t, 462e-17f, 462e-18

  overdosage/poisoning with, 473e-8t
Metoclopramide
  adverse effects of, 260, 261, 2611
  for constipation, 61
  drug interactions of, 246e-2t
  for gastroparesis, 260, 260t, 2427
  for migraine, 2591, 2592t
  for nausea and vomiting, 62, 103e-25, 474
  parenteral, 2592t
Metoprolol
  for aortic dissection, 1641
  for arrhythmias, 1479t, 1480t
  dosage of, 1479t, 1480t
  drug interactions of, 246e-12
  genetic variations in response to, 39t, 40
  for heart failure, 1512t
  for hypertension, 1624t
  for ischemic heart disease, 1589t
  metabolism of, 34t
  for migraine prevention, 2594t
  for myocardial infarction, 1604
  overdosage/poisoning with, 473e-9t
  pharmacology of, 1479t, 1480t
Metrifonate, 246e-5t, 246e-10
Metronidazole
  for acne rosacea, 352
  action of, 931t, 932f, 933
  adverse effects of, 246e-5t, 353, 938t, 944, 2687t
  for amebiasis, 1367, 1367t
  for anaerobic bacterial infections, 1101, 1101t
  for bacterial vaginosis, 873t, 875
  for *C. difficile* infection, 860, 860t
  for clostridial infections, 991t, 994
  for *D. fragilis* infection, 1409
  drug interactions of, 246e-5t, 939t, 944
  for epidural abscess, 767t
  for febrile neutropenia, 103e-23
  for *Giardia* infections, 268, 1406
  in *H. pylori* eradication, 1042t, 1922, 1922t
  for hepatic encephalopathy, 2066
  indications for, 246e-5t, 941t, 944, 945t
  for intraabdominal infections, 767t
  for intracranial infections, 780t
  for Ludwig's angina, 233
  for meningitis, 887t, 889, 889t
  for necrotizing fasciitis, 832t
  for osteomyelitis, 841t
  for pelvic inflammatory disease, 878, 878t
  for peritonitis, 848
  for postpartum endomyometritis, 50
  for pouchitis in IBD, 1960
  in pregnancy and lactation, 246e-5t, 937t
  resistance to
    in anaerobic bacteria, 1101
    in *H. pylori*, 1042
    mechanisms of, 931t, 934
    prevalence of, 941t, 944
  for *T. vaginalis* infection, 871, 873t, 874, 1409
  for tetanus, 986
  for Vincent's angina, 233
METs (metabolic equivalent tasks), 1585t, 1587, 1587t
Metyrapone, 611–612, 2273, 2318
Mevalonate kinase, 372e-8t
Mevalonate kinase deficiency, 2215
Mexiletine
  adverse effects of, 1480t, 2682t
  for arrhythmias, 1480t, 1498
  dosage of, 1480t
  for hyperkalemic periodic paralysis, 462e-18
  metabolism of, 34t
  for myotonia, 462e-11
  for neuropathy, 2682t
  for pain, 95, 2672
  for paramyotonia congenita, 462e-18
  pharmacology of, 1480t

Zafirlukast, 2119, 2124
Zalcitabine (ddC), 1276f
Zaleplon, 191, 473e-10t
Zanamivir
  action of, 214e-5, 214e-9, 215e-1
  adverse effects of, 1213
  for influenza prophylaxis, 215e-2t, 1213t, 1214
  for influenza treatment, 215e-2t, 215e-5, 233, 1213, 1213t
  pharmacology of, 215e-1
  resistance to, 215e-1, 215e-2t
Z-disk, genetic defects of, 1555t
Zeaxanthin, 96e-7
Zenker's diverticulum, 256, 259, 1903, 1903f
ZES. *See* Zollinger-Ellison syndrome (ZES)
Zeta-associated protein 70 (ZAP70) deficiency, 2109
Zicam, 14e-3
Zidovudine (AZT)
  action of, 1273
  for adult T-cell leukemia/lymphoma, 225e-5
  adverse effects of, 1273, 1274t
    anemia, 1262
    cutaneous, 379
    hepatotoxicity, 2023, 2030
    hypertrichosis, 380
    myopathy, 439, 462e-20, 462e-20t, 1267, 2197, 2199, 2218t
    nail disorders, 380, 1263
    neutropenia, 417
    oral pigmentation, 240t
  drug interactions of, 246e-2t, 246e-4t, 798
  for HIV infection, 50, 1223, 1273, 1274t
  molecular structure of, 1276f
  resistance to, 1279f
Zieve's syndrome, 2059
Zika virus infection, 1307t, 1314
Zileuton, 40
Zimbabwe, 13e-6–7
Zinc, **96e-9**
  absorption of, 96e-9
  deficiency of. *See* Zinc deficiency
  functions of, 96e-9
  for macular degeneration, 205
  recommended intake of, 95e-3t
  reference range for, 2766t
  supplements. *See* Zinc supplements
  tolerable upper intake level of, 96e-9t
  toxicity of, 96e-9t, 96e-10
  for Wilson's disease, 2520–2521, 2520t, 2625
Zinc deficiency
  clinical features of, 96e-9, 96e-9t, 461
  esophageal cancer risk and, 533
  global considerations in, 96e-9, 461
  treatment of, 461
  with vitamin A deficiency, 96e-6
Zinc gluconate lozenges, 96e-9
Zinc oxide exposure, 1692
Zinc sulfate flotation, 152e-1
Zinc supplements
  adverse effects of, 215
  for hepatic encephalopathy, 2066
  for olfactory dysfunction, 216
  parenteral, 98e-6t
  for zinc deficiency, 96e-9
Ziprasidone, 2721, 2722t
Zirconium, 367
Ziv-aflibercept, 102e-5t, 103e-21
Z-line deformity, 2136
Z lines, of sarcomere, 265e-5
Zn-DTPA, 263e-6t, 263e-7
ZNRD1 gene, in HIV infection, 1240t
Zoledronate (zoledronic acid)
  adverse effects of, 426e-4, 2499–2500
  for bone loss prevention in prostate cancer, 586
  for hypercalcemia, 314, 610, 2480t, 2481
  for multiple myeloma, 717
  for osteoporosis management/prevention, 2499––2500, 2500f, 2504
  for Paget's disease of bone, 426e-3–4, 426e-3t
Zollinger-Ellison syndrome (ZES), **568**, **1927**
  clinical features of, 559t, 1927–1928
  cobalamin malabsorption in, 646
  diagnosis of, 568, 1928, 1928t, 1929t, 1940t
  differential diagnosis of, 1924, 1927–1928
  epidemiology of, 1927
  gastroduodenal ulcer in, 262
  incidence of, 559t
  MEN 1 and, 562, 568, 1927–1928, 2336–2337
  pathophysiology of, 559t, 1927
  treatment of, 568–569, 1929
  tumor distribution in, 559t, 1927
  tumor localization in, 1928–1929, 1929t
Zolmitriptan, 2591, 2592t, 2593t, 2595
Zolpidem, 65, 191, 473e-10t, 476e-4
Zonisamide, 261, 473e-10t, 2555t, 2766t
Zoster. *See* Herpes zoster (shingles)
Zoster ophthalmicus. *See* Herpes zoster ophthalmicus
Zoster sine herpetica, 1185
Zotarolimus, 296e-2
Z-scores, 2493, 2493f
Zungarococha virus, 1309t
Zwitterionic characteristics, 849
Zygomycosis. *See* Mucormycosis
